The analysis also indicates that, in addition to the overall reduction in SOx emissions, the proposed project will result in less than significant increases of VOC, CO, NOx, PM10 and PM2.5 emissions during the operational phase of the proposed project. Because operational emissions do not exceed the project-specific air quality significance thresholds, which also serve as the cumulative significance thresholds, they are not considered to be cumulatively considerable (CEQA Guidelines §15064 (h)(1)). Further, the amount of emission reductions to be achieved by the proposed project for SOx will, at the very least, meet the emission reduction projections and commitments made in the AQMP. Even though the proposed project will cause a temporary and significant adverse increase in air emissions during the construction phase and less than significant increases in air emissions during the operation phase, the temporary net increase in construction emissions combined with the total permanent emission reductions projected overall during operation would not interfere with the air quality progress and attainment demonstration projected in the AQMP. Further, based on regional modeling analyses performed for the 2007 AQMP, implementing control measures contained in the 2007 AQMP, in addition to the air quality benefits of the existing rules, is anticipated to bring the District into attainment with all national and most state ambient air quality standards by the year 2023. Therefore, cumulative operational air quality impacts from the proposed project, previous amendments and all other AQMP control measures considered together, are not expected to be significant because implementation of all AQMP control measures is expected to result in net emission reductions and overall air quality improvement. This determination is consistent with the conclusion in the 2007 AQMP Final Program EIR that cumulative air quality impacts from all AQMP control measures are not expected to be significant (SCAQMD, 2007). Therefore, there will be no significant cumulative adverse operational air quality impacts from implementing the proposed project.

Though the proposed project involves combustion processes which could generate GHG emissions such as CO2, CH4, and N2O, the proposed project does not affect equipment or operations that have the potential to emit other GHGs such as SF6, HFCs or PFCs. Relative to GHGs, implementing the proposed project is expected to increase GHG emissions that exceed the SCAQMD's GHG significance threshold for industrial sources. In addition, implementing

the proposed project is expected to generate significant adverse cumulative GHG air quality impacts. The GHG analysis for the proposed project can be found in the "Global Climate Change Impacts" section of this chapter.

CUMULATIVE MITIGATION MEASURES: The analysis indicates that, in addition to the overall reduction in SOx emissions, the proposed project will result in slight increases of VOC, CO, NOx, PM10 and PM2.5 emissions during the operational phase of the proposed project. However, no pollutant emissions exceed the applicable significance thresholds during operation for the proposed project. Thus, there are no adverse significant cumulative air quality impacts with the operational phase of the proposed project and as such, no cumulative mitigation measures for operation are required.

The analysis also indicates that the VOC, NOx, and PM10 emissions will exceed the applicable significance thresholds during construction. As a result, the proposed project is expected to have significant cumulative adverse construction air quality impacts. Mitigation measures that focus on the VOC, NOx, and PM10 emissions that may be generated during construction are required to minimize the significant air quality impacts associated with construction activities. Therefore, feasible mitigation measures to reduce emissions associated with construction activities at the affected facilities are necessary to control emissions from heavy construction equipment and worker travel. While the mitigation measures may reduce emissions associated with construction activities at the affected facilities to the maximum extent feasible, none will avoid the significant impact or reduce the impact to less than significant.

The following construction mitigation measures are required for construction activities from the proposed project:

<u>On-Road Mobile Sources</u>

AQ-1 Develop a Construction Emission Management Plan for each affected facility to minimize emissions from vehicles including, but not limited to: consolidating truck deliveries; scheduling deliveries to avoid peak hour traffic conditions; describing and truck routing; describing deliveries including logging delivery times; describing entry/exit points; identifying locations of parking; identifying construction schedule; and prohibiting truck idling in excess of five consecutive minutes or another time-frame as allowed by the California Code of Regulations, Title 13 §2485 - CARB's Airborne Toxic Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling.

<u>Off-Road Mobile Sources</u>

AQ-2 Suspend all construction activities that generate air pollutant emissions during first stage smog alerts.

AQ-3 Prohibit construction equipment from idling longer than five minutes.

AQ-4 Use electricity or alternate fuels for on-site mobile equipment instead of diesel equipment to the extent feasible.

AQ-5 Tune-up construction equipment and maintain a two- to four-degree retard diesel engine timing, to the extent feasible.

AQ-6 Use electric welders to avoid emissions from gasoline or diesel welders in portions of the project sites where electricity is available.

AQ-7 Use on-site electricity rather than temporary power generators in portions of the project sites where electricity is available.

AQ-8 Prior to use in construction, each project applicant will evaluate the feasibility of retrofitting the large off-road construction equipment that will be operating for substantial periods. Retrofit technologies such as particulate traps, selective catalytic reduction, oxidation catalysts, air enhancement technologies, etc., will be included in the evaluation. These technologies will be required if they are certified by CARB and/or USEPA and are commercially available and can feasibly be retrofitted onto construction equipment.

GLOBAL CLIMATE CHANGE IMPACTS

Significant changes in global climate patterns have recently been associated with global warming, an average increase in the temperature of the atmosphere near the Earth's surface, attributed to accumulation of GHG emissions in the atmosphere. GHGs trap heat in the atmosphere, which in turn heats the surface of the Earth. Some GHGs occur naturally and are emitted to the atmosphere through natural processes, while others are created and emitted solely through human activities. The emission of GHGs through the combustion of fossil fuels (i.e., fuels containing carbon) in conjunction with other human activities, appears to be closely associated with global warming. State law defines GHG to include the following: carbon dioxide (CO2), methane (CH4), nitrous oxide (N2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF6) (HSC §38505(g)). The most common GHG that results from human activity is CO2, followed by CH4 and N2O.

Traditionally, GHGs and other global warming pollutants are perceived as solely global in their impacts and that increasing emissions anywhere in the world contributes to climate change anywhere in the world. A study conducted on the health impacts of CO2 "domes" that form over urban areas cause increases in local temperatures and local criteria pollutants, which have adverse health effects[73].

The analysis of GHGs is a much different analysis than the analysis of criteria pollutants for the following reasons. For criteria pollutants, the significance thresholds are based on daily emissions because attainment or non-attainment is primarily based on daily exceedances of applicable ambient air quality standards. Further, several ambient air quality standards are based on relatively short-term exposure effects on human health (e.g., one-hour and eight-hour standards). Since the half-life of CO2 is approximately 100 years, for example, the effects of GHGs occur over a longer term which means they affect the global climate over a relatively long time frame. As a result, the SCAQMD's current position is to evaluate the effects of GHGs over a longer timeframe than a single day (i.e., annual emissions). GHG emissions are typically

[73] Jacobsen, Mark Z. "Enhancement of Local Air Pollution by Urban CO2 Domes," Environmental Science and Technology, as describe in Stanford University press release on March 16, 2010 available at: http://news.stanford.edu/news/2010/march/urban-carbon-domes-031610.html.

considered to be cumulative impacts because they contribute to global climate effects. GHG emission impacts from implementing the proposed project were calculated at the project-specific level for both Options 1 and 2. For example, installation of SOx control equipment such as WGSs and DGSs has the potential to increase the electricity, fuel, and water use which will in turn increase CO2 emissions.

The SCAQMD has convened a "Greenhouse Gas CEQA Significance Threshold Working Group" to consider a variety of benchmarks and potential significance thresholds to evaluate GHG impacts. On December 5, 2008, the SCAQMD adopted an interim CEQA GHG Significance Threshold for projects where SCAQMD is the lead agency (SCAQMD, 2008). This interim threshold is set at 10,000 metric tons of CO2 equivalent emissions (MTCO2eq) per year. The SCAQMD prepared a "Draft Guidance Document – Interim CEQA GHG Significance Thresholds" that outlined the approved tiered approach to determine GHG significance of projects (SCAQMD, 2008, pg. 3-10). The first two tiers involve: 1) exempting the project because of potential reductions of GHG emissions allowed under CEQA; and, 2) demonstrating that the project's GHG emissions are consistent with a local general plan. Tier 3 proposes a limit of 10,000 MTCO2eq per year as the incremental increase signifying significance for industrial projects where SCAQMD is the lead agency (SCAQMD, 2008, pg. 3-11). Tier 4 (performance standards) is yet to be developed. Tier 5 allows offsets that would reduce the GHG impacts to below the Tier 3 brightline threshold. Projects with incremental increases below this threshold will not be cumulatively considerable.

As indicated in Chapter 3, combustion processes generate GHG emissions in addition to criteria pollutants. The following analysis mainly focuses on directly emitted CO2 because this is the primary GHG pollutant emitted during the combustion process and is the GHG pollutant for which emission factors are most readily available. CO2 emissions were estimated using emission factors from CARB's EMFAC2007 and Offroad2007 models and USEPA's AP-42. In addition, CH4 and N20 emissions were also estimated and are included in the overall GHG calculations. No other GHGs are expected to be emitted because the proposed project does not affect equipment or operations that have the potential to emit other GHGs such as SF6, HFCs or PFCs.

Installation of SOx control equipment as part of implementing the proposed project is expected to generate construction-related CO2 emissions. In addition, based on the type and size of equipment affected by the proposed project, CO2 emissions from the operation of the SOx control equipment are likely to increase from current levels due to electricity, fuel and water use. The proposed project will also result in an increase of GHG operational emissions produced from additional truck hauling and deliveries necessary to accommodate the additional solid waste generation and increased use of supplies such as catalyst and caustic.

For the purposes of addressing the GHG impacts of the proposed project, the overall impacts of CO2eq emissions from the project were estimated and evaluated from the earliest possible initial implementation of the proposed project with construction beginning in 2012. Once the proposed project is fully implemented, the potential SOx emission reductions would continue through the end of the useful life of the equipment. The analysis estimated CO2eq emissions from all sources subject to the proposed project (construction and operation) from the beginning of the proposed project (2012) to the end of the project (2019). The beginning of the proposed project was assumed to be no sooner than 2012, since installing SOx control equipment such as a WGS takes considerable advance planning and engineering. Full implementation of the proposed

project is expected to occur by the end of 2018 since all the affected facilities would be required to comply with the proposed project by January 1, 2019, such that any installed or modified SOx controls would be constructed and operational by the final compliance date. Thus, once construction is complete and the equipment is operational, no further changes in CO2eq emissions are anticipated.

For Options 1 and 2 respectively, Tables 4-10 and 4-12 summarize the CO2eq impacts from both construction activities and operation activities per facility and Tables 4-11 and 4-13 summarize the same CO2eq impacts per source category. In all of these tables, the CO2eq impacts from construction were amortized over a 30-year period. The peak operational emissions are based on the operations of the SOx control equipment plus the anticipated increase in truck hauling and deliveries as a result of maintaining the SOx control equipment. Though the peak operational emissions are assumed to occur as early as 2013, all operational emissions are expected to occur by the end of year 2018 because the compliance date of the proposed project is January 1, 2019.

[3] A negative number means a reduction in usage or demand.

As demonstrated in Tables 4-10 and 4-12, none of the affected facilities individually exceed the industrial GHG significance threshold of 10,000 MT/day. However, the GHG emissions from the project as a whole under Options 1 and 2, respectively, exceed the threshold and therefore, the proposed project is considered to have adverse significant GHG impacts. Because the proposed project is expected to generate construction-related CO2 emissions, and the operational phase of the proposed project is also expected to generate additional GHG emissions, adverse significant GHG cumulative impacts from the proposed project are expected.

GHG MITIGATION: If the proposed project gets implemented, the analysis indicates that there will be a significant increase in GHG emissions. Because, there are adverse significant GHG impacts from the proposed project and as such, feasible GHG mitigation measures are required.

GHG mitigation measures for industrial sources are under development. However, there are some existing GHG reducing protocols that have been approved or adopted by various organizations and some of these are already used in the SCAQMD's SoCal Climate Solutions Exchange, a voluntary program where facilities in the district can undertake projects to voluntarily reduce GHG emissions in advance of any regulatory requirement. In order to participate in the exchange, the GHG reductions need to be real, additional (surplus), quantifiable, verifiable, permanent over a specific time, and enforceable. These early reductions can be helpful to facilities that would need offsets for GHG mitigation.

The California Climate Action Registry (CCAR) is currently developing the following protocols: 1) bus rapid transit; 2) blended cement; 3) tidal wetland sequestration (farms converting to wetlands). CCAR is also evaluating several categories for potential protocol development, including waste diversion, local government operations, boiler efficiency; and truck stop electrification. CCAR has been asked to look at other areas, such as waste water biogas, natural

gas pipelines, agricultural soil sequestration, and CO2 capture and storage, and those will be evaluated in the future.

In addition, the California Air Pollution Control Officers Association (CAPCOA) has suggested that lead agencies develop a "Green List of Projects" (Green List) to be consistent with and achieve the goals of AB 32 and to encourage projects that can provide overall GHG emission reduction benefits. Of the Green List projects, especially in consideration that compliance with the proposed project could result in the installation of water-intensive scrubbers, recycled water projects and the utilization of recycled water seem to be among the most direct ways to mitigate GHG emissions for the proposed project. Specifically, the energy it would take to treat and convey reclaimed water to a facility (e.g., 1,200 kWh/MMgallons[74]) is approximately 10 times less than the amount of energy it would take for potable water (e.g., 12,700 kWh/MMgallons[75]) to be supplied, conveyed and distributed. Thus, for each facility that will have future access to recycled water and uses reclaimed wastewater to satisfy the water demands for the proposed project and in turn, mitigate CO2eq emissions, less GHG emissions would be generated for the operational water use/conveyance and operational wastewater generation portions of the proposed project.

Based on the preceding discussion, the following mitigation measure will apply to the proposed project:

GHG-1 When SOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the SOx control equipment.

GHG-2 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the SOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be supplied to the project.

For Options 1 and 2 respectively, Tables 4-14 and 4-16 summarize the mitigated CO2eq impacts from both construction activities and operation activities per facility and Tables 4-15 and 4-17 summarize the same CO2eq impacts per source category. Thus, utilizing recycled water to mitigate GHG emissions from the proposed project would result in a savings of GHG emissions of 597 MT/year for Option 1 and 430 MT/year for Option 2.

As demonstrated in Tables 4-14 and 4-16, none of the affected facilities individually exceed the GHG industrial significance threshold of 10,000 MT/yr before or after mitigation. However, the GHG emissions from the project as a whole under Options 1 and 2, respectively, exceed the threshold and therefore, the proposed project is considered to have adverse significant GHG impacts after mitigation. Because the proposed project is expected to generate construction-related CO2eq emissions, and the operational phase of the proposed project is also expected to

[2] GHGs from temporary construction activities are amortized over 30 years.
[3] A negative number means a reduction in usage or demand.

While there may be additional measures that could eventually be imposed upon sources with potential increases in GHG emissions, CARB is adopting measures pursuant to AB 32 that would require the maximum technically feasible and cost-effective GHG emission reductions

from most of the industry categories affected by the proposed project. CEQA Guidelines §15364 defines "feasible" as "capable of being accomplished in a successful manner within a reasonable period of time…" Specifically, CARB's adopted "early action measures" include a measure to limit methane emissions from landfills, which SCAQMD staff will enforce. CARB also has adopted a Low Carbon Fuel Standard for motor vehicle fuels. As of this writing, it is expected that CARB will adopt in October 2010 a GHG reduction cap and trade program that will apply to projects that will need to receive permits, including any projects that may occur as a result of amending the SOx RECLAIM program. CARB greenhouse gas reduction measures are required to "achieve the maximum technologically feasible and cost-effective greenhouse gas reductions from sources or categories of sources" (Health & Safety Code §38560). CARB has published a scoping plan, as required by Health and Safety Code §38561, that identifies additional measures CARB intends to adopt that will reduce GHG emissions. The scoping plan is required to identify measures that will achieve "the maximum feasible and cost-effective reductions of greenhouse gas emissions by 2020." (Health and Safety Code §38561(b)).

All CARB GHG measures are required to meet the "maximum feasible and cost-effective" reductions test. This test is equally as stringent as the CEQA definition of "feasible." Given that CARB has been working on this statutory mandate for four years, and has an entire office and staff devoted to GHG rulemaking, it would not be feasible for SCAQMD staff to develop generally applicable GHG reduction measures that go beyond CARB measures. Thus, application of CARB rules will require the maximum feasible GHG reductions for existing sources.

SCAQMD rules do not currently require BACT for GHGs, except GHGs that are also ozone depleters. (See SCAQMD Rule 1303(a)(1).) However, by 2011, SCAQMD will be required under federal law to specify GHG BACT for larger sources of GHG emissions. On June 3, 2010, EPA published in the Federal Register its Greenhouse Gas Tailoring Rule (75 FR 31513).

EPA has stated that because there is no national ambient air quality standard for CO2, or any of the other primary GHGs, and EPA does not plan to promulgate any, the "nonattainment" NSR program that applies to criteria pollutants will not apply to GHGs[76]. However, for a NSR program that applies to attainment pollutants, prevention of significant deterioration (PSD) will also apply. PSD applies to any "major stationary source" of pollutants subject to regulation under the federal CAA. Accordingly, because EPA has promulgated its GHG reduction rules for motor vehicles, GHGs will become a pollutant subject to regulation under the federal Clean Air Act. EPA has issued its interpretation that GHGs become regulated pollutants as of the time the motor vehicle rule becomes effective (i.e., January 2011). SCAQMD staff concludes it would not be feasible to begin requiring GHG BACT prior to January 2011, because it would be necessary to amend the agency's rules in order to do so.

Under the federal CAA, the PSD definition of major source includes facilities with the potential to emit 250 tons per year of the relevant pollutant, or 100 tons per year for certain specified types of facilities. At these thresholds of GHG emissions, EPA estimated that there would be approximately 80,000 additional PSD permit actions annually nationwide. In addition, the Title V permit program for existing sources is also triggered when a pollutant becomes regulated under the federal Clean Air Act, and its threshold is 100 tons per year. At that threshold of GHG

[76] "Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule; Proposed Rule" ("Tailoring Rule Proposal") 74 FR 55292, 55297 (October 27, 2009).

emissions, EPA estimated that there would be an additional six million Title V permits nationwide. Since the SCAQMD encompasses about five percent of the nation's population, SCAQMD would be expected to experience at least 300,000 additional Title V permits added to its system. By way of contrast, SCAQMD has currently about 600 Title V permits. Thus, the permit inventory would increase by 500 times. It is not feasible for SCAQMD to issue and enforce 500 times as many Title V permits as it already has. Because of the anticipated burdens on permitting agencies and facilities from applying the federal CAA thresholds literally, EPA proposed to use the doctrines of administrative necessity and absurd results to support establishing a different threshold for BACT (PSD) and Title V applicability. EPA's initial proposal was a threshold of 25,000 MT/yr GHG for applicability, and a significance threshold for modifications triggering PSD in the range of 10,000 to 25,000 MT/yr. In the final rule, EPA recognized that it had substantially underestimated the impacts of applying the Title V and PSD programs at the 25,000 MT/yr level and decided to adopt a phased-in approach.

In Step 1, which begins January 2, 2011, only facilities that would already be subject to Title V or PSD would be subject to GHG requirements under these programs. In addition, a facility modification would only trigger PSD for GHGs if the modification resulted in an increase of 75,000 MT/yr CO2eq. Therefore, SCAQMD would begin to require GHG BACT for sources already subject to PSD and having a GHG increase of 75,000 MT/yr or more, effective January 2, 2011.

In Step 2, which begins July 1, 2011, facilities with a potential to emit 100,000 MT/yr CO2eq or more would be subject to Title V and PSD, regardless of whether they would otherwise be subject to these programs as a result of emissions of other pollutants. Therefore, SCAQMD would begin to require GHG BACT for all new and modified facilities having the potential to emit 100,000 MT/yr CO2eq and having an increase of at least 75,000 MT/yr CO2eq effective July 1, 2011.

For future phases of the program, EPA has committed to a further rulemaking to be completed in 2012 which will consider whether it is feasible to further lower the thresholds for GHG coverage under these programs. However, it is unknown at this time whether the thresholds will be further lowered. EPA has, however, committed that the threshold will not be lowered below 50,000 MT/yr CO2eq until at least May 1, 2016.

Although the definition of federal BACT for PSD sources is somewhat different from the definition of BACT that SCAQMD uses for nonattainment NSR, this definition is still at least as stringent as the CEQA definition of feasible. Pursuant to federal CAA §169(3) (42 U.S.C. §7479(3)), the term "best available control technology" means in pertinent part "an emission limitation based on the maximum degree of reduction of each pollutant subject to regulation under this chapter emitted from or which results from any major emitting facility, which the permitting authority, on a case-by-case basis, taking into account energy, environmental, and economic impacts and other costs, determines is achievable for such facility through application of production processes and available methods, systems, and techniques, including fuel cleaning, clean fuels, or treatment or innovative fuel combustion techniques for control of each such pollutant." Therefore, GHG BACT is at least as stringent as CEQA's definition of feasible mitigation, which similarly allows consideration of economic, technological and environmental factors. Thus, application of BACT will require the maximum feasible reductions of GHGs at new or modified sources.

All 11 facilities that may be affected by the proposed project are Title V facilities and nine of the 11 facilities currently hold PSD permits. However, because the potential GHG increases at each affected facility are individually well below EPA's tiered thresholds, GHG BACT would not be required for any of the individual facilities making facility modifications to comply with the proposed project.

Further, in light of the uncertainty associated with the effects of the proposed project on individual facilities whose operators have not submitted any applications for permits to construct as a result of the proposed project, the adoption and implementation of feasible mitigation beyond the requirement of using recycled water when available will not reduce significant air quality and climate change impacts to a less-than-significant level. In other words, it would not be feasible for the SCAQMD to attempt to develop and impose additional GHG mitigation measures for the myriad of source categories that may be affected by the proposed project. Accordingly, the project-level and cumulative impacts identified as significant in this chapter cannot feasibly be mitigated to a less-than-significant level and remain significant and unavoidable.

ENERGY IMPACTS

Significance Criteria

Impacts to energy and mineral resources will be considered significant if any of the following criteria are met:

- The project conflicts with adopted energy conservation plans or standards.
- The project results in substantial depletion of existing energy resource supplies.
- An increase in demand for utilities impacts the current capacities of the electric and natural gas utilities[77].
- The project uses non-renewable resources in a wasteful and/or inefficient manner.

Project-Specific Construction and Operation Impacts: In order to achieve the overall net air quality benefit (SOx emission reductions) from implementing the proposed project, the affected facility operators may choose to modify existing equipment by retrofitting with air pollution control equipment or modifying existing control equipment. As part of these modifications, electricity could be utilized to operate certain construction equipment, such as welders, if access to electricity is available. (In fact, utilizing electricity for welders, in lieu of diesel welders is encouraged and required as part of mitigation for air quality construction emissions.) Further, after installation of any SOx control equipment to comply with the proposed project, increased operational demand for energy used for operating the main control equipment plus ancillary equipment such as pumps, controllers, et cetera is expected.

Any additional electricity that may be needed as part of implementing the proposed project is typically supplied by each affected facility's local electrical utility and if applicable, supplemented by the facility's own cogeneration unit. Similarly, any additional natural gas that may be needed is typically supplied by each affected facility's local natural gas utility, unless the facility self-generates fuel on-site. Table 4-18 summarizes the energy sources and local utility service providers for the 11 affected facilities.

[77] SCAQMD's Energy Threshold is considered an increase at or above one percent of available supply.

Energy information as it relates to construction and operational activities was derived as part of the air quality analysis in this chapter and the calculations are shown in Appendix B of this ~~Draft~~ Final PEA. If the potential SOx controls are installed and operated on a per facility and per source category basis, respectively, Tables 4-19 and 4-20 summarize the estimated impacts on operational natural gas and electricity use for Option 1. Similarly, Tables 4-21 and 4-22 summarize the estimated impacts on operational natural gas and electricity use for Option 2.

	TOTAL	**-4.1***	**100,721**

* A negative number means a reduction in usage or demand.

Table 4-22
Option 2: Operational Energy Use By Source Category

Equipment/ Source Category	Natural Gas (MMBTU/day)	Electricity (kWh/day)
FCCUs	0	0
SRU/TGUs	30	21,721
Refinery Boilers/Heaters	-34*	22,649
Petroleum Coke Calciner	0	17,711
Glass Melting Furnaces	0	5,694
Sulfuric Acid Manufacturing	0	9,659
Cement Kilns	0	23,288
TOTAL	**-4.1***	**100,721**

* A negative number means a reduction in usage or demand.

For Option 1, the analysis shows an overall decrease in natural gas demand of approximately 4.1 MMBTU per day (equivalent to 0.004 MMcf/day) and an overall increase in electricity demand of 203,938 kWh/day (equivalent to 204 MWh/day) for the affected source categories. For Option 2, the analysis shows an overall decrease in natural gas demand of approximately 4.1 MMBTU/day (equivalent to 0.004 MMcf/day) and an overall increase in electricity demand of 100,721 kWh/day (equivalent to 101 MWh/day) for the affected source categories.

In addition, as part of operation for some WGSs, NaOH caustic soda solution is required. For Option 1 of the proposed project, 13.24 tons per day of NaOH is estimated to be needed and for Option 2, 8.79 tons per day of NaOH may be needed. NaOH is produced locally by several chemical processing companies and as such, is locally available for transport. Further, it is likely that the existing local caustic manufacturers can handle the proposed increase in caustic for the entire project. To accommodate the estimated increase in caustic demand, the chemical processing companies may need to increase production, which, in turn, will use more electricity. It takes approximately 2,500 kWh to produce one metric ton of NaOH. Thus, the approximate amount of additional electricity that may be needed to produce additional caustic to meet the needs of Option 1 and Option 2 of the proposed project, are 30,023 kWh/day and 19,932 kWh/day, respectively, and are calculated as follows:

Option 1:

$$\frac{13.24 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{Ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = \mathbf{30{,}023 \text{ kWh/day}}$$

Option 2:

$$\frac{8.79 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{Ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = \mathbf{19{,}932 \text{ kWh/day}}$$

The overall electricity needed to implement both Options 1 and 2 of the proposed project as summarized in Tables 4-19, 4-20, 4-21 and 4-22 include the amount of electricity that may be needed to produce additional NaOH. To determine if the operational energy use is significant for Options 1 and 2, the total for natural gas and electricity was compared to the threshold fuel supply as shown in Table 4-23. California utilities and non-utilities have the ability to receive approximately 9,330 MMcf/day of natural gas[78], [79], [80]. Since both Options 1 and 2 of the proposed project do not exceed the SCAQMD's energy threshold of one percent of supply for both natural gas and electricity, the proposed project is expected to have less than significant energy impacts. Further, because the increase in electricity demand for both Options 1 and 2 is below the SCAQMD's energy significance threshold of one percent above available supplies, any increased demand that may result from either Option 1 or 2 of the proposed project can be met with the existing electrical capacity at each of the affected facilities. Lastly, based on this analysis, it is not anticipated that new or substantially altered power utility systems will need to be built to accommodate any additional electricity demands created by either Option 1 or 2 of the proposed project.

Table 4-23
Total Projected Natural Gas and
Electricity Impacts for Operation Activities

Operation Activity	Total Energy Usage per Activity	
	Natural Gas[a]	Electricity
Option 1	-0.004 MMcf	204 MWh/day = 8.5 MW (instantaneous)
Threshold Fuel Supply	9,330 MMcf [b]	8,362 MW [c] (instantaneous)
% of Fuel Supply	-0.00004 %	0.1%
Significant (Yes/No) [d]	No	No
Option 2	-0.004 MMcf	101 MWh/day = 4.2 MW (instantaneous)
Threshold Fuel Supply	9,330 MMcf [b]	8,362 MW [c] (instantaneous)
% of Fuel Supply	-0.00004 %	0.05%
Significant (Yes/No) [d]	No	No

[a] A negative number is a reduction in the use of natural gas consumption.

[b] Natural Gas Infrastructure Draft Staff Paper, California Energy Commission, May 2009 (CEC-200-2009-004-SD). http://www.energy.ca.gov/2009publications/CEC-200-2009-004/CEC-200-2009-004-SD.PDF

[c] California Energy Demand 2008-2018 Staff Revised Forecast, Staff Final Report, California Energy Commission, , November 2007 (CEC-200-2007-015-SF2). See Form 1.4 b, Peak Demand by LSE: summer Peak Demand Coincident with Planning Area Peak for the following agencies/areas: SCE (Anaheim, Azusa, Banning, Colton, Metropolitan Water District, Rancho Cucamonga, Riverside and Vernon), Cities of Burbank, Glendale and Pasadena, and LADWP. http://www.energy.ca.gov/2007publications/CEC-200-2007-015/CEC-200-2007-015-SF2.PDF

[d] SCAQMD's Energy Threshold for both Natural Gas and Electricity is 1% of Supply.

KEY: MMcf = million standard cubic feet
MW(Megawatt) = 1 MW = 1,000 kilowatts (KW)

In addition, Table 4-24 presents a summary of the total projected fuel usage (i.e., diesel and gasoline) for both construction and operational activities for both Options 1 and 2 of the proposed project. For Option 1, the analysis shows an overall increase in diesel and gasoline use of approximately 3,763 gallons per day and 1,354 gallons per day, respectively. Similarly for Option 2, the analysis shows an overall increase in diesel and gasoline use of approximately 3,397 gallons per day and 1,354 gallons per day, respectively.

Since neither Option 1 nor Option 2 of the proposed project exceeds the SCAQMD's energy threshold of one percent of supply for both diesel and gasoline fuels, both Option 1 and Option 2 of the proposed project are expected to have less than significant energy impacts due to fuel use. Further, once construction is completed, the fuel use projected during the temporary phases (e.g., Phase I: Demolition and Phase II: Construction) will end and only the fuel use for truck trips associated with chemical deliveries and solid waste removal activities during Phase III: Operations will continue. Thus, any potential adverse fuel impacts will be less than what has been analyzed during the peak for the proposed project.

Table 4-24
Total Projected Fuel Usage

Activity	Total Fuel Usage per Activity (gallons/day)	
	Diesel	**Gasoline**
Proposed Project - Option 1: Phase I - Demolition Overlapping with Phase II - Construction at Four Facilities (Construction Equipment and Workers Vehicles)	1,360	1,354
Proposed Project - Option 1: Phase III: Operation (Chemical Deliveries & Solid Waste Removal)	2,403	0
Total Usage for Proposed Project - Option 1:	3,763	1,354
Threshold Fuel Supply[a]	1,086,000,000	6,469,000,000
% of Fuel Supply	0.0003%	0.00002%
Significant (Yes/No)[b]	No	No
Proposed Project - Option 2: Phase I - Demolition Overlapping with Phase II - Construction at Four Facilities (Construction Equipment and Workers Vehicles)	1,360	1,354
Proposed Project - Option 2: Phase III: Operation (Chemical Deliveries & Solid Waste Removal)	2,037	0
Total Usage for Proposed Project - Option 2:	3,397	1,354
Threshold Fuel Supply[a]	1,086,000,000	6,469,000,000
% of Fuel Supply	0.0003%	0.00002%
Significant (Yes/No)[b]	No	No

[a] Year 2000 California Energy Commission (CEC) projections. Construction activities in future years would yield similar results.
[b] SCAQMD's energy threshold for both diesel and gasoline is 1% or more of supply.

The proposed project is not subject to any existing energy conservation plans. If any facility that is subject to the proposed project is also subject to energy conservation plans, it is not expected that the proposed project will affect in any way or interfere with that individual facility's ability to comply with its energy conservation plan or energy standards. Further, project construction and operation activities will not utilize non-renewable resources in a wasteful or inefficient manner. Lastly, it is expected that the installation and operation of any equipment used to comply with the proposed project will also comply with all applicable existing energy standards.

In summary, the energy impacts from both Option 1 and Option 2 of the proposed project are concluded to be less than significant.

Project-Specific Mitigation: Less than significant adverse impacts associated with energy are expected from the proposed project during both construction and operation, so no mitigation measures are required.

Level of Significance After Mitigation: The analysis concluded that the energy impacts from implementing the proposed project are considered to be adverse, but less than significant. Therefore, mitigation measures are not required.

Cumulative Energy Impacts: Because the project-specific energy impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative energy impacts.

Cumulative Mitigation Measures: None required.

HAZARDS AND HAZARDOUS MATERIALS IMPACTS

The NOP/IS (see Appendix A) determined that the proposed project has the potential to generate significant adverse hazards and hazardous materials impacts. The hazard and hazardous materials impacts associated with the operation of the proposed project are potentially significant and the impacts are evaluated in this section.

Hazards and Hazardous Materials Significance Criteria

The impacts associated with hazards and hazardous materials will be considered significant if any of the following occur:

- Non-compliance with any applicable design code or regulation.
- Non-conformance to National Fire Protection Association (NFPA) standards.
- Non-conformance to regulations or generally accepted industry practices related to operating policy and procedures concerning the design, construction, security, leak detection, spill containment or fire protection.
- Exposure to hazardous chemicals in concentrations equal to or greater than the Emergency Response Planning Guideline (ERPG) 2 levels.

PROJECT-SPECIFIC IMPACTS - HAZARD ANALYSIS: Several components with regard to reducing SOx emissions by installing new or modifying existing SOx controls or by using SOx reducing additives as part of implementing the proposed project may affect the use, storage and transport of hazards and hazardous materials during operational-related activities. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of implementing the proposed project.

The key effects of implementing the proposed project and the determination of which aspects involve hazards and hazardous materials focus on: 1) the anticipated increase of substances used to operate the new SOx controls and the anticipated replacement and/or supplement of substances used to modify or upgrade existing SOx control systems; and, 2) the increased capture of hazardous substances as part of the overall SOx reduction effort. For example, with FCCU source category, Option 1 of the proposed project may involve the use of NaOH caustic, a TAC, to operate WGSs and Option 2 may involve an anticipated increase of catalyst use (e.g., as SOx reducing additives) and the catalyst fines collected overall (comprised of PM10) may qualify as either a hazardous material or hazardous waste. In addition, implementation of the

various control techniques for multiple source categories may have the effect of reducing hazardous components of SOx, such as capturing more SO2, SO3, H2S, COS, and ethyl- and methyl-mercaptans. Table 4-25 contains a summary of the substances that may be used, stored and transported as part of implementing the proposed project.

Table 4-25
Substances Used by SOx Control Technologies

Equipment/ Source Category	Current SOx Control Technology	Substances Currently Used for SOx Control	Proposed SOx Control Technology	Proposed Substances To Be Used/Increased for SOx Control
FCCU	SOx Reducing Additives	Specialty Catalyst	Option 1: WGSs Option 2: Increase amount of SOx Reducing Additives	Option 1: NaOH Caustic Option 2: Specialty Catalyst
SRU/TGU	Sour Water Strippers, Claus Units with Tail Gas Treatment, Amine Absorbers	Catalyst and Amines (MDEA and TG-10)	3 WGSs for 2 facilities (new)	Soda Ash Caustic
SRU/TGU	Sour Water Strippers	Catalyst	1 Selective Oxidation Catalyst system for 1 facility (new)	ESx Catalyst
Sulfuric Acid	Catalytic Converter	Catalyst	1 WGS for 1 facility (new)	NaOH Caustic

Cement Kiln	None	None	2 DGS (Limestone Absorber) for 1 facility (new)	Limestone
Refinery Boilers/ Heaters	Amine Absorbers	Amines (MEA & DEA)	3 FGTs by Sulfinol Conversion for 3 facilities (modified)	Sulfolane and DIPA
Refinery Boilers/ Heaters	Amine Absorbers	Amine (MEA) & Caustic (NaOH)	2 FGTs by Merox Treatment Upgrades for 2 facilities (modified)	1. Merox Catalyst 2. NaOH Caustic
Refinery Boilers/ Heaters	Amine Absorbers	Amine (MDEA)	1 FGT by Amine Additive for 1 facility (modified)	TG-10 amine

Key: WGS = Wet Gas Scrubber; DGS = Dry Gas Scrubber; FGT = Fuel Gas Treatment

Hazard Safety Regulations

Notwithstanding implementation of the proposed project, operators of each affected facility must comply or continue to comply with various regulations, including Occupational Safety and Health Administration (OSHA) regulations (29 Code of Federal Regulations (CFR) Part 1910) that require the preparation of a fire prevention plan, and 20 CFR Part 1910 and CCR Title 8 that require prevention programs to protect workers who handle toxic, flammable, reactive, or explosive materials. In addition, §112 (r) of the CAA Amendments of 1990 [42 United States Code (USC) 7401 et. seq.] and Article 2, Chapter 6.95 of the California HSC require facilities that handle listed regulated substances to develop Risk Management Programs (RMPs) to prevent accidental releases of these substances. If any of the affected facilities has already prepared an RMP, it may need to be revised to incorporate any changes that may be associated with the proposed project. The Hazardous Materials Transportation Act is the federal legislation that regulates transportation of hazardous materials.

A number of physical or chemical properties may cause a substance to be hazardous. With respect to determining whether any material identified in Table 4-25 is hazardous, each Material Safety Data Sheet (MSDS) has also been consulted for the National Fire Protection Association (NFPA) 704 hazard rating system (i.e. NFPA 704). NFPA 704 is a "standard (that) provides a readily recognized, easily understood system for identifying specific hazards and their severity using spatial, visual, and numerical methods to describe in simple terms the relative hazards of a material. It addresses the health, flammability, instability, and related hazards that may be presented as short-term, acute exposures that are most likely to occur as a result of fire, spill, or similar emergency[81]." In addition, the hazard ratings per NFPA 704 are used by emergency personnel to quickly and easily identify the risks posed by nearby hazardous materials in order to help determine what, if any, specialty equipment should be used, procedures followed, or precautions taken during the first moments of an emergency response. The scale is divided into four color-coded categories, with blue indicating level of health hazard, red indicating the flammability hazard, yellow indicating the chemical reactivity, and white containing special codes for unique hazards such as corrosivity and radioactivity. Each hazard category is rated on a scale from 0 (no hazard; normal substance) to 4 (extreme risk). Table 4-26 summarizes what the codes mean for each hazards category.

It is expected that the operators of affected facilities will comply with all applicable design codes and regulations, conform to NFPA standards, and conform to policies and procedures concerning leak detection containment and fire protection. Therefore, no significant adverse offsite hazard impacts are expected as explained in the following sections.

[81] National Fire Protection Association, FAQ for Standard 704. http://www.nfpa.org/faq.asp?categoryID=928&cookie%5Ftest=1#23057

Table 4-26
NFPA 704 Hazards Rating Codes

Hazard Rating Code	Health (Blue)	Flammability (Red)	Reactivity (Yellow)	Special (White)
4 = Extreme	Very short exposure could cause death or major residual injury (extreme hazard)	Will rapidly or completely vaporize at normal atmospheric pressure and temperature, or is readily dispersed in air and will burn readily. Flash point below 73°F.	Readily capable of detonation or explosive decomposition at normal temperatures and pressures.	**~~W~~** = Reacts with water in an unusual or dangerous manner.
3 = High	Short exposure could cause serious temporary or moderate residual injury	Liquids and solids that can be ignited under almost all ambient temperature conditions. Flash point between 73°F and 100°F.	Capable of detonation or explosive decomposition but requires a strong initiating source, must be heated under confinement before initiation, reacts explosively with water, or will detonate if severely shocked.	**OXY** = Oxidizer
2 = Moderate	Intense or continued but not chronic exposure could cause temporary incapacitation or possible residual injury.	Must be moderately heated or exposed to relatively high ambient temperature before ignition can occur. Flash point between 100°F and 200°F.	Undergoes violent chemical change at elevated temperatures and pressures, reacts violently with water, or may form explosive mixtures with water.	**SA** = Simple asphyxiant gas (includes nitrogen, helium, neon, argon, krypton and xenon).
1 = Slight	Exposure would cause irritation with only minor residual injury.	Must be heated before ignition can occur. Flash point over 200°F.	Normally stable, but can become unstable at elevated temperatures and pressures	
0 = Insignificant	Poses no health hazard, no precautions necessary	Will not burn	Normally stable, even under fire exposure conditions, and is not reactive with water.	

Hazard Impacts on Water Quality

A spill of any hazardous material that is used and stored at any of the affected facilities could occur under upset conditions such as an earthquake, tank rupture, or tank overflow. Spills could also occur from corrosion of containers, piping and process equipment; and leaks from seals or gaskets at pumps and flanges. A major earthquake would be a potential cause of a large spill. Other causes could include human or mechanical error. Construction of the vessels and foundations in accordance with the Uniform Building Code Zone 4 requirements helps structures to resist major earthquakes without collapse, but may result in some structural and non-structural damage following a major earthquake. Any facility with storage tanks on-site is currently required to have emergency spill containment equipment and would implement spill control

measures in the event of an earthquake. Storage tanks typically have secondary containment such as a berm which would be capable of containing 110 percent of the contents of the storage tanks. Therefore, should a rupture occur, the contents of the tank would be collected within the containment system and pumped to an appropriate storage tank.

Spills at the affected facilities would generally be collected within containment areas. Large spills outside of containment areas at the affected facilities are expected to be captured by the process water system where they could be collected and controlled. Spilled material would be collected and pumped to an appropriate tank or sent off-site if the materials cannot be used on-site. Because of the containment system design, spills are not expected to migrate from the spill site and as such, potential adverse water quality hazard impacts are considered to be less than significant.

Project Specific Impacts

The following discussion describes the hazards profile for each substance involved with proposed SOx control equipment or techniques.

Hazard Impacts from SOx Reducing Additives

FCCUs are operated at six refineries in the Basin (e.g., at Facilities A through F). Operation of FCCUs is reliant on a catalyst, sometimes referred to as a "base catalyst" or an "equilibrium catalyst" in order to function. FCCU operators may also mix in additives (also catalysts) to change the composition of the flue gas to reduce emissions such as NOx and SOx. As shown in Table 4-27, four of the six facilities that operate FCCUs currently use SOx reducing additives.

Table 4-27
Summary of Current SOx Reducing Additive Use for FCCUs at Affected Refineries

	Refinery					
	A	**B**	**C**	**D**	**E**	**F**
Uses SOx Reducing Additive?	Yes	Yes	No	No	Yes	Yes

The amount of SOx reducing additives introduced into each FCCU varies from unit to unit, depends on the inlet concentration of SO2, and is typically a percentage of the fresh base catalyst addition rate, which can range between five and 10 weight percent, but can go as high as 20 weight percent for handling SOx emission spikes. As with the base catalyst, eventually the SOx reducing additives cannot be regenerated and as such, need to be replaced with a fresh supply. The constant replenishment of base catalyst and SOx reducing additives means a constant generation of solid waste in the form of catalyst fines. The composition of the catalyst fines in the solid waste is mostly comprised of base catalyst with a small portion (approximately two to ten weight percent) attributed to SOx reducing additives.

Nonetheless, for any additional increase in the use of SOx reducing catalysts in any FCCU, a directly proportional reduction in the amount of FCCU base catalyst used would be expected because the capacity of the FCCU regenerator vessel is a fixed volume. This means that the total amount of catalysts (FCCU base catalyst plus SOx reducing catalyst) used is expected to remain about the same. Thus, the amount of catalyst-based solid waste generated and disposed of or recycled from the FCCU process as part of utilizing additional SOx reducing catalyst is also expected to remain about the same. To accommodate the increased amount of SOx reducing additives that may be needed for the proposed project (up to 500 pounds per day per affected

facility), there will be a slight increase in the frequency of truck transportation trips (one trip per day) to deliver fresh SOx reducing additives to each affected facility.

SOx reducing additives are made up of a mixture of metal oxide compounds such as aluminum oxide, magnesium oxide, cerium oxide, ceric oxide, magnesium aluminate, magnesium vanadate, cerium vanadium oxide, calcium aluminate, and ferric oxide. There are two manufacturers of SOx reducing additives for FCCUs: Grace Davison and Intercat. Grace Davison manufacturers a product called "Super DeSOx" and Intercat's products are called "SOxGetter" and "Super SOxGetter." While these products vary from each other, in general, they are similar in composition to FCCU "base catalyst" in that they are made of metal oxide compounds and that they are compatible with SOx reducing additives. Located on the MSDS for Intercat's SOx reducing additives (e.g., "SOxGetter" and "Super SOxGetter"), the hazards ratings are as follows: health is rated 1 (slightly hazardous), flammability is rated 0 (none) and reactivity is rated 0 (none). Similarly, the hazard ratings for Grace Davison's "Super DESOX" additive are: health is rated 2 (moderately hazardous), flammability is rated 0 (none) and reactivity is rated 0 (none).

The particular composition of the catalyst used (base plus additives), combined with the metals content of the flue gas, will determine the hazard rating and whether the spent catalyst mixture is considered a hazardous material or hazardous waste. For example, if nickel is deposited on the catalyst, the hazard rating is 2 for health (moderately toxic), 4 (extreme fire hazard) for flammability, 1 for reactivity (slightly hazardous if heated or exposed to water). In this example, the spent catalyst may qualify as a hazardous material, but if it can be recycled or reused by another industry (such as manufacturing Portland cement), then it would not be considered as hazardous waste. However, spent catalyst that is considered hazardous waste must be disposed of in a Class III landfill.

Survey responses from each of the affected refineries have indicated that none of the catalyst-based solid waste generated is classified as hazardous. For this reason, any increase in the use of SOx reducing additives would not be expected to substantially change the composition of the current waste generated. There are two facilities that current do not use SOx reducing additives, Facilities C and D. Facility C no longer uses SOx reducing additives because the facility's current SOx control system can achieve the five ppm SOx levels at the outlet. Should operators of Facility D decide to start using SOx reducing additives, based on the experience with the other refineries, it is unlikely that the composition of the solid waste generated would change from non-hazardous waste to hazardous waste. (Facility D currently sends its catalyst fines to a cement plant for recycling.)

Spent catalyst fines from FCCUs can be transported to a Class III landfill for disposal as non-hazardous waste. However, due to the heavy metal content and relatively high cost of catalysts, recycling can be more lucrative than disposal. As such, the catalyst fines currently collected from the FCCUs at each of these affected facilities are loaded into a truck and transported to a local cement plant for recycling. Thus, any increase or new use of SOx reducing additives as a result of the proposed project is not expected to substantially change the profile of the catalysts fines in a way that would prevent the spent catalyst mixture from continuing to be recycled. For this reason, the affected facilities are expected to continue to recycle the spent catalyst that may be generated as a result of the proposed project.

Although recycling may be the more popular consideration, it is possible that facilities may choose to dispose of the spent catalyst in a landfill. The composition and type of the catalyst will determine the type of landfill that would be eligible to handle the disposal. For example, catalysts with a metal structure would be considered a metal waste, like copper pipes, and not a hazardous waste. Therefore, metal structure catalysts would not be a regulated waste requiring disposal in a Class I landfill unless it is friable or brittle. As ceramic-based catalysts contain a fiber-binding material, they are not considered friable or brittle and, thus, would not be a regulated waste requiring disposal in a Class I landfill. Furthermore, typical catalyst materials are not considered to be water soluble, which also means they would not require disposal in a Class I landfill. In both cases, spent catalyst would not require disposal in a Class I landfill.

Based on the aforementioned information, it is likely that spent catalysts would be considered a "designated waste," which is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state (California Code of Regulations, Title 23, Chapter 3, Subparagraph 2522(a)(1)). Depending on its actual waste designation, spent catalysts would likely be disposed of in a Class II landfill or a Class III landfill that is fitted with liners. According to the Final Program EIR for the 2007 AQMP (SCAQMD, 2007), total Class III landfill waste disposal capacity in the District is approximately 97,269 tons per day, many of which have liners and can handle Class II and Class III wastes.

Disposal of spent catalyst would typically involve crushing the material and encasing it in concrete prior to disposal. Since it is expected that most spent catalysts will be recycled and regenerated, it is anticipated that there will be sufficient landfill capacity in the District to accommodate disposal of any spent catalyst materials.

In conclusion, the hazards and hazardous materials impacts due to the use of SOx reducing additives and the handling of the spent catalyst for recycling or disposal as non-hazardous waste is expected to be less than significant for the proposed project.

Caustic

For any operator that chooses to install a WGS, hazardous materials may be needed to operate the WGSs depending on the source category and additional solid waste is expected to be generated. Caustic is a key ingredient needed for the operation of a WGS; it is the most widely used substance for several SOx control applications spanning multiple equipment/source categories. While there are several types of caustic solutions that can be used in WGS operations, caustic made from sodium hydroxide (NaOH) is the most commonly used for WGSs for FCCUs, sulfuric acid units, coke calciners, and glass melting furnaces.

For WGSs that may be installed to control SOx from SRU/TGUs, the caustic used in the WGS is made from soda ash, instead of NaOH. Soda ash is the common name for sodium carbonate (Na2CO3), a non-toxic, non-cancerous, and non-hazardous substance. Located on the MSDS for Na2CO3, the hazards ratings are as follows: health is rated 2 (moderate), flammability is rated 0 (none) and reactivity is rated 0 (none).

NaOH caustic is also used with Merox catalyst treatment for FGT of refinery boilers and heaters. (For a discussion on Merox systems, see the "Amines" discussion in the following section.) NaOH is a toxic air contaminant (TAC); it is also a non-cancerous but acutely hazardous

substance. Located on the MSDS for NaOH (50 percent by weight), the hazards ratings are as follows: health is rated 3 (highly hazardous), flammability is rated 0 (none) and reactivity is rated 1 (slightly hazardous).

As previously analyzed in the Air Quality discussion, for "worst-case" operations, 13.24 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate eight of the 11 total WGSs plus two FGTs for Option 1 and 8.79 tons per day of NaOH is estimated to be needed to operate four of the seven total WGSs plus two FGTs for Option 2. In addition, even though the facilities that may be affected by the proposed project may already use NaOH elsewhere in their facilities, for the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for every WGS installed or FGT system using Merox catalyst. However, of the 11 facilities affected by the proposed project overall, only nine facilities were projected to have an increased demand in NaOH use for WGS operations or FGT modifications under Option 1 and only five facilities were projected to have an increased demand in NaOH use for WGS operations or FGT modifications under Option 2.

As previously summarized in Tables 4-8 and 4-9, for each facility that was projected to increase the use in the acutely hazardous substance NaOH under Options 1 and 2, respectively, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities for either option. Because the screening level for NaOH was not exceeded for any of the affected facilities for either option, no significant hazards and hazardous materials impacts with respect to NaOH uses are expected from the proposed project. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed.

It is expected that the affected facilities will receive NaOH from a local supplier located in the greater Los Angeles area. Deliveries of NaOH (50 percent by weight) would be made by tanker truck via public roads. The maximum capacity of a NaOH tanker truck is approximately 6,000 gallons. The projected onsite storage capacity and consumption rates of NaOH are summarized in Tables 4-8 and 4-9 and the projected annual deliveries are summarized in Tables 4-28 and 4-29. Based on the annual deliveries estimates, each facility is not expected to exceed the peak daily of one delivery per day per facility. However, the "worst-case" assumption for a peak daily delivery frequency from a supplier would be to deliver 6,000 gallons of NaOH to each of four facilities to fill four new NaOH tanks on the same day. Regulations for the transport of hazardous materials by public highway are described in 49 CFR §§ 173 and 177.

To accommodate the increased demand in NaOH, there will be an increase in truck deliveries to supply NaOH to the facilities that need it. Tables 4-28 and 4-29 summarize the annual and peak daily truck deliveries needed to supply NaOH for Options 1 and 2 of the proposed project, respectively. Based on the volume of NaOH solution (50 percent by weight) needed, the calculations assume that one 10,000 gallon capacity storage tank will be installed at each affected facility for NaOH storage. The amount of annual deliveries is based on the assumption that one delivery truck can hold 6,000 gallons per truck load. While the number of annual NaOH deliveries will vary based on each facility's needs, the peak daily truck deliveries would be one truck per day per facility.

Table 4-28
Option 1: Summary of NaOH Deliveries

Facility ID	Daily Increase in NaOH Demand (tons/day)	Annual Increase in NaOH Demand (tons/year)	Annual NaOH Deliveries [1] (truck trips/year)
A	0.81	294	8
B	1.17	427	12
C	0	0	0
D	0.44	160	5
E	0.45	164	5
F	2.02	738	20
G	2.90	1,060	28
H	3.37	1,228	32
I	0.79	289	8
J	1.30	473	13
K	0	0	0
Total	**13.24**	**4,833**	**131**

[1] Annual NaOH deliveries are calculated based on one delivery truck holding 6,000 gallons per truck load. For example, for Facility A: 294 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 46,045 gal/year x 1 truck/6,000 gallons = 8 trucks/year.

Table 4-29
Option 2: Summary of NaOH Deliveries

Facility ID	Daily Increase in NaOH Demand (tons/day)	Annual Increase in NaOH Demand (tons/year)	Annual NaOH Deliveries [1] (truck trips/year)
A	0	0	0
B	0	0	0
C	0	0	0
D	0.44	160	5
E	0	0	0
F	0	0	0
G	2.90	1,060	28
H	3.37	1,228	32
I	0.79	289	8
J	1.30	473	13
K	0	0	0
Total	**8.79**	**3,210**	**86**

[1] Annual NaOH deliveries are calculated based on one delivery truck holding 6,000 gallons per truck load. For example, for Facility A: 294 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 46,045 gal/year x 1 truck/6,000 gallons = 8 trucks/year.

All of the refineries (Facilities A through G) currently receive NaOH from local suppliers located in the greater Los Angeles area. For the remaining facilities that do not currently use NaOH, but will begin using it, the local suppliers are expected to be able to accommodate the additional demand. As is currently the case with existing NaOH deliveries, deliveries of additional NaOH would be made to each facility by tanker truck via public roads. NaOH is typically delivered in 6,000 gallon trucks, so the proposed project would not introduce any new transportation hazards for NaOH.

The onsite storage and handling of NaOH creates the possibility of an accidental spill and release of NaOH. However, because NaOH has such a low vapor pressure (6.33 mm Hg at 40 ^{o}C or 104

^{o}F) when compared to water (55.3 mm Hg at 40 ^{o}C or 104 ^{o}F) at the same temperature, any spill of NaOH would not be expected to evaporate faster than water. Thus any spill of NaOH would be expected to stay in liquid form and would not likely exceed the ERPG-2 vapor concentration of five milligrams per cubic meter for NaOH. Further, operators at each affected facility who construct a new NaOH storage tank will need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release due to tank rupture. Thus, any spill of NaOH would not be expected to migrate beyond the boundaries of the berm on-site. Thus, any spill of NaOH is not expected to present a potential offsite public and sensitive receptor exposure. Lastly, since NaOH is not a flammable compound, other types of heat-related hazard impacts such as fires, explosions, boiling liquid – expanding vapor explosion (BLEVE) are not expected to occur and, therefore, will not be evaluated as part of this hazards analysis.

In conclusion, the hazards and hazardous materials impacts due to the use, tank rupture and the accidental release of NaOH will be less than significant for the proposed project.

Limestone

In DGSs, a dry calcium- and sodium-based alkaline powdered sorbent is used to absorb SO2 from the flue (outlet) gas stream. Only one source category, cement kilns located at Facility K, may be retrofitted with two DGSs to comply with the proposed project. The sorbent expected to be used in the DGSs will be limestone. Limestone is an existent component needed for manufacturing cement and Facility K is located adjacent to its own limestone quarry. Thus, the additional limestone that would be needed to operate the DGSs (approximately three tons per day under both Options 1 and 2 of the proposed project) is expected to also be supplied by the quarry. Limestone, also known as calcium carbonate (CaCO3), is a non-toxic, non-cancerous, and non-hazardous substance. The NFPA has not assigned a rating for calcium carbonate.

As the limestone absorbs the sulfur compounds in the flue gas, a solid waste by-product is produced that is comprised of 90 percent calcium sulfate (CaSO4) and 10 percent calcium sulfite (CaSO3). Both CaSO4 and CaSO3 are non-toxic, non-cancerous, and non-hazardous substances. Located on the MSDSs for CaSO4 and CaSO3, the NFPA hazards ratings are the same for both compounds, as follows: health is rated 1 (slightly hazardous), flammability is rated 0 (none) and reactivity is rated 0 (none).

Operation of the DGSs is expected to generate approximately two tons per day of this by-product mixture. Since CaSO4 is stable at high temperatures and since most of the by-product is comprised of CaSO4, the by-product can be re-introduced into the kiln with the raw feed to manufacture cement. Even though some SO2 may be liberated from the CaSO3 portion of the by-product as it enters the kiln feed, the DGS will be able to re-capture the SO2. Any portion of the solid waste by-product generated that cannot be re-introduced into the kiln, can either be sent to a landfill, used for agricultural purposes, or mixed in with aggregate. In any case, the solid waste by-products that may be generated from this process would not be considered hazardous waste.

In conclusion, the hazards and hazardous materials impacts due to the use of limestone and the recycling or disposal of its solid, non-hazardous waste by-product mixture of CaSO4 and CaSO3, is expected to be less than significant for the proposed project.

Selective Oxidation Catalyst

The proposed project may result in the replacement of an existing catalytic emission reduction system with a selective oxidation catalyst system to treat flue gas from a SRU/TGU. The selective oxidation catalyst, ESx, is a proprietary product manufactured by EmeraChem. ESx, is a platinum- and titanium-based catalyst that is manufactured in module form. The modules consist of six inch-by-six inch coated ceramic blocks that are stacked in a fixed bed. The amount of blocks that are needed depends on the amount of exhaust gas being treated and the amount of sulfur in the exhaust. The ESx catalyst acts as a sulfur trap and is continuously regenerated. At the end of its useful life, the spent ESx modules are replaced with fresh modules. The precious metals in the spent catalyst are reclaimed from the modules and the remaining material is crushed, and then recycled or disposed of in a landfill as non-hazardous waste. The NFPA has not assigned a rating for the ESx catalyst, but the MSDS for ESx indicates that it is non-hazardous according to the definition for "health hazard" and "physical hazard" provided in the OSHA Hazard Communication Law (29 CFR Part 1910).

Only one facility, Facility A, may consider using ESx catalyst, the equivalent to 400 pounds per year, for its SRU/TGU system. Delivery of the catalyst modules can be accomplished in one truck trip. In conclusion, the hazards and hazardous materials impacts due to the use of ESx catalyst and the recycling or disposal of the spent catalyst modules, is expected to be less than significant for the proposed project.

Sulfuric Acid

There are two facilities that manufacture sulfuric acid (H2SO4) in the Basin (Facilities C and J). H2SO4 is a considered a hazardous substance because it is a poisonous, corrosive liquid that is highly reactive with water. H2S04 has proposed risk values for both cancer/chronic and acute effects per SCAQMD Rule 1401. The International Agency for Research on Cancer (IARC) has classified "strong inorganic acid mists containing sulfuric acid" as a known human carcinogen, (IARC category 1). However, this classification applies only to mists containing sulfuric acid, and not to sulfuric acid or sulfuric acid solutions. H2SO4 is also a regulated substance pursuant to CalARP threshold under certain conditions. Located on the MSDSs for H2SO4 solution (52 to 100 percent, weight), the NFPA hazards ratings are as follows: health is rated 3 (highly hazardous), flammability is rated 0 (none), reactivity is rated 2 (moderately hazardous), and the special category is rated as water reactive.

Implementation of the proposed project may result in operators of Facility C upgrading their existing Cansolv unit by increasing the amount of steam throughput and operators of Facility J installing a WGS to further reduce SOx from their H2SO4 processes. While the nature of this source category involves the manufacture of a highly hazardous substance, the amount of H2SO4 produced is limited by the amount of available feedstock and the permit limits in place. Thus, the possible changes that may occur at the back-end of each of the affected facilities to reduce SOx are not anticipated to increase the production of H2SO4. Therefore, no changes to the existing hazards setting with respect to H2SO4 production is expected to result from the proposed project

Cansolv is a proprietary hydroxyalkyamine mixture that contains the following hazardous materials: 1,4-dioxane, acetaldehyde, formaldehyde, ethylene glycol, and ethylene oxide. All of these substances are regulated hazardous substances though the NFPA has not assigned hazards ratings to Cansolv. Acetaldehyde, ethylene glycol, and ethylene oxide are assigned chronic/cancer risk values while 1,4-dioxane and formaldehyde are assigned risk values for both

chronic/cancer and acute exposures pursuant to SCAQMD Rule 1401. In addition, all of these substances except ethylene glycol are regulated by CalARP.

Though Cansolv is considered a hazardous material, it is important to note that the potential modifications to the Cansolv Unit at Facility C will focus on increasing the amount of steam input to the existing amine regenerator tower. The amount of steam introduced into the unit is inversely proportional to the amount of SO2 in the exhaust stream (i.e., more steam in, less SO2 in the exhaust gas). The increase in steam to the amine regenerator tower will not change the amount of Cansolv amine currently used in the process and further, is not expected to involve the use of any new hazardous substance or increase any hazardous waste that may already be generated by the unit.

Lastly, the installation of a WGS at Facility J will increase the amount of NaOH caustic, a hazardous material. However, the hazards analysis for the increased use of NaOH for the sulfuric acid source category along with the other source categories that may employ WGSs is previously addressed in the "Caustic" discussion in this section.

In conclusion, installing new controls and upgrading existing controls for sulfuric acid manufacturing units will not entail the use of hazardous materials or require any disposal of hazardous waste. Thus, based on the preceding analysis, the hazards and hazardous materials impacts are expected to be less than significant for the proposed project.

Amines

Amine absorbers are currently utilized for reducing SOx emissions as part of FGT or as part of SRU/TGU systems operated at refineries. The type of amine used in these absorbers varies from process to process and sometimes the amines are paired up with a proprietary catalyst such as Merox for additional SOx control. The most common amines are DEA, MDEA, and MEA and their use is limited to removing H2S and CO2 from gas streams. While none of these amines can remove mercaptans, DEA and MEA can be used to remove COS.

Of these three amines, DEA is the only amine that is a TAC and carcinogenic. DEA is regulated as a hazardous compound/regulated substance per SCAQMD's Rule 1401. Located on the MSDSs for DEA, the NFPA hazards ratings are follows: health is rated 1 (slightly hazardous), flammability is rated 1 (slightly flammable) and reactivity is rated 0 (none). Located on the MSDSs for MEA, the NFPA hazards ratings are follows: health is rated 3 (highly hazardous), flammability is rated 2 (moderately flammable) and reactivity is rated 0 (none). The NFPA has not assigned a rating for MDEA.

The proposed project may entail modifications to FGT systems at five refineries. These modifications are summarized in Table 4-30.

Table 4-30
Summary of Potential FGT Modifications Per Facility

Facility ID	FGT Modification
A	Convert two DEA absorbers to Sulfinol
C	Convert all MEA absorbers to Sulfinol
D	Add Merox treatment to existing MEA and NaOH treatment of coker off-gas
E	Convert all DEA absorbers to Sulfinol
F	Add TG-10 to existing MDEA amine in the absorber
G	Add Merox treatment to existing MEA and NaOH treatment of coker off-gas

Sulfinol

The Sulfinol process is a proprietary mixed solvent process that removes H2S, CO2, COS, mercaptans and other organic sulfur compounds from gas streams. Sulfinol is the combination of two proprietary solvents mixed with water (25 percent by weight): 1) Sulfolane (tetrahydrothiopene dioxide) (25 percent by weight); and, 2) di-isopropanolamine (DIPA) (50 percent by weight). Neither Sulfolane nor DIPA are regulated substances pursuant to SCAQMD Rule 1401 or CalARP. Located on the MSDSs for Sulfolane, the NFPA hazards ratings are as follows: health is rated 1 (slightly hazardous), flammability is rated 1 (slightly flammable) and reactivity is rated 0 (none). Similarly, the NFPA hazards ratings for DIPA are as follows: health is rated 3 (highly hazardous), flammability is rated 1 (slightly flammable) and reactivity is rated 0 (none).

Operators of three facilities (Facilities A, C and E) may consider implementing a solvent change out to Sulfinol. If implemented, each of these facilities may use their existing amine storage tanks to store Sulfinol instead.

Facility A currently uses approximately 127,000 gallons per year of DEA for two absorbers. By switching over to Sulfinol for these units, the DEA will no longer be necessary and instead the usage of Sulfinol will be approximately 131,000 gallons per year. Since DEA is a regulated TAC with chronic/cancer risks, the Sulfinol change out at Facility A may reduce the existing toxics hazards for DEA amine use in their two absorbers.

Facility C currently uses approximately 288,000 gallons per year of MEA for their absorbers. By switching over to Sulfinol for these units, the MEA will no longer be necessary and instead the usage of Sulfinol will be approximately 278,000 gallons per year. While the solvent change out from MEA to Sulfinol is not expected to change existing health hazard, it is expected to reduce the flammability from moderately flammable to slightly flammable.

Facility E currently uses approximately 375,000 gallons per year of DEA for their absorbers. By switching over to Sulfinol for these units, the DEA will no longer be necessary and instead the usage of Sulfinol will be approximately 385,000 gallons per year. Since DEA is a regulated TAC with chronic/cancer risks, the Sulfinol change out at Facility E may reduce the existing toxics hazards for DEA amine use in their absorbers.

Implementing FGT modifications at three facilities by employing a Sulfinol amine swap is expected to reduce the hazards profile of the affected units because Sulfinol is less hazardous (e.g., less toxic when compared to DEA and less flammable when compared to MEA) than the existing amines currently used in these units. Thus, based on the preceding analysis, the hazards and hazardous materials impacts relative to the use of Sulfinol are expected to be less than significant for the proposed project.

Merox

Merox is a proprietary caustic scrubbing technology used for removing mercaptans and residual H2S from fuel gas. A Merox unit will typically consist of a column with three sections: 1) pre-wash; 2) extraction; and, 3) water wash. Feedstock enters the bottom of the column in the prewash section. The gas flows upward in the column where NaOH caustic is injected into the extraction section; the caustic acts as an absorbing agent to capture the mercaptans and convert them to sodium mercaptides. The spent caustic solution is regenerated by an oxidizer unit with catalyst injection to convert the mercaptides to disulfide oil. The disulfide oil is separated and sent elsewhere within the refinery for further processing while the regenerated caustic soda is returned to the extraction section of the column.

The addition of a Merox system to an existing absorber system means that the current amine solution will continue to be used. For example, in the cases of Facility D and G, MEA amine and NaOH caustic are currently used to treat the coker off-gas. Even if a Merox system is installed at each facility, MEA and NaOH will continue to be used and the amount of MEA needed will remain unchanged. The amount of NaOH needed will increase. It is important to note that Facility D and G already use NaOH in their FGT systems. However, the conversion to Merox technology will increase the amount of NaOH needed at these facilities. The analysis for the potential increases in NaOH for FGT are addressed in the previous discussion in the "Caustic" section. Lastly, Merox catalyst will be needed, approximately eight pounds per day or 3,000 pounds per year per facility, for the caustic regeneration portion of the Merox process.

Merox catalyst is comprised of a proprietary, cobalt-based reagent (a trade secret cobalt phthalocyanine sulfonate compound) that contains mostly water. The MSDS for Merox catalyst indicates that none of the ingredients in the catalyst have components that are classified or regulated by OSHA or by the United States National Toxicology Program (NTP). However, all of the ingredients in the catalyst are registered on the Toxic Substances Control Act (TSCA) Chemical Substance Inventory. Cobalt compounds are also specified as toxic chemicals under SARA Section 313 and may be subject to the Toxic Release Inventory (TRI) reporting requirements under 40 CFR 372. In addition, cobalt compounds are regulated pursuant to the State of California's Proposition 65 noticing requirements. Cobalt and cobalt compounds are not regulated by SCAQMD Rule 1401 or CalARP. The NFPA has not assigned a rating for Merox catalyst. Lastly, Merox catalyst is not listed in the USEPA's RCRA regulations because it does not possess any of the four identifying characteristics of hazardous waste (e.g., ignitibility, corrosivity, reactivity or toxicity).

Implementing FGT modifications at two facilities by installing Merox treatment systems is not expected to change the hazards profile of the affected units because Merox is not regulated as a hazardous substance. Thus, based on the preceding analysis, the hazards

and hazardous materials impacts relative to the use of Merox are expected to be less than significant for the proposed project. .

TG-10

TG-10 is a proprietary amine additive that is specifically designed for meeting a 10 ppmv H2S specification in tail gas treating applications. Operators of Facility F may consider adding TG-10 to the existing MDEA amine used in their absorber. Facility F is estimated to need approximately 11 gallons per day or 4,000 gallons per year of TG-10 to mix in with the MDEA for their absorber.

As previously mentioned, MDEA is not a TAC and it is not a regulated substance pursuant to SCAQMD Rule 1401 or CalARP. The NFPA has not assigned a rating for MDEA. Located on the MSDS for TG-10, the NFPA hazards ratings are follows: health is rated 1 (slightly hazardous), flammability is rated 1 (slightly flammable) and reactivity is rated 0 (none). TG-10 is not considered hazardous according to DOT Guidelines and it contains no chemical subject to SARA Title III Section 313 supplier notification requirements.

Implementing FGT modifications at one facility by adding TG-10 to the existing MDEA amine is not expected to change the hazards profile of the affected unit because TG-10 contains mostly MDEA, which is not regulated as a hazardous substance. Thus, based on the preceding analysis, the hazards and hazardous materials impacts relative to the use of the MDEA/TG-10 blend are expected to be less than significant for the proposed project.

In conclusion, implementing the various FGT modifications at six facilities is not expected to make the existing hazards setting worse at the affected units. Thus, based on the preceding analysis, the hazards and hazardous materials impacts relative to the use of amines and Merox catalyst are expected to be less than significant for the proposed project.

Reduction of SOx Emissions

In addition, implementation of the proposed project is designed to reduce overall SOx emissions by up to 6.21 tons per day. Components of the SOx reductions are SO2, SO3, H2S, COS and mercaptans (ethyl- and methyl-). The following is a brief discussion of whether the components of SOx are hazardous.

SO2

SO2 is not a carcinogen or a TAC, but it is a regulated compound per CalARP. Located on the MSDSs for SO2, the NFPA hazards ratings are as follows: health is rated 3 (serious hazard), flammability is rated 0 (none) and reactivity is rated 0 (none). A reduction of SO2 would be beneficial because it would result in a reduction in a serious health hazard.

SO3

SO3 is a TAC with proposed risk values for cancer or non-cancer that are pending approval. SO3 is also a regulated compound per CalARP. The NFPA hazards ratings for SO3 are as follows: health is rated 3 (serious hazard), flammability is rated 0 (none) and reactivity is rated 2 (moderately reactive). A reduction of SO3 would be beneficial because it would result in a reduction of a toxic compound and a serious health hazard.

H2S

H2S is a carcinogen and a TAC with cancer/chronic and acute risk values per SCAQMD Rule 1401. H2S is also a regulated compound per CalARP. The NFPA hazards ratings for H2S are as follows: health is rated 4 (severely hazardous), flammability is rated 4 (severely flammable) and reactivity is rated 0 (none). H2S is listed as an extremely hazardous substance (EHS) subject to state and local reporting under Section 304 of SARA Title III. A reduction of H2S would be beneficial because it would result in a reduction of a toxic, carcinogenic compound and a severely hazardous health and flammability hazard.

COS

COS is not a carcinogen or a TAC, but it is a regulated compound per CalARP. Located on the MSDSs for COS, the NFPA hazards ratings are as follows: health is rated 2 (moderately hazardous), flammability is rated 0 (none) and reactivity is rated 1 (slightly reactive). A reduction of COS would be beneficial because it would result in a reduction of a moderate health hazard.

Mercaptans

Ethyl- and methyl-mercaptans are not carcinogenic or TACs, but they are regulated compounds per CalARP. The NFPA hazards ratings for ethyl-mercaptan are as follows: health is rated 1 (slightly hazardous), flammability is rated 4 (severely flammable) and reactivity is rated 1 (slightly reactive). The NFPA hazards ratings for methyl-mercaptan are as follows: health is rated 3 (highly hazardous), flammability is rated 4 (severely flammable) and reactivity is rated 0 (none). A reduction of mercaptans would be beneficial because it would result in a reduction of a severely flammable hazard for both ethyl- and methyl-mercaptans and a reduction of a high health hazard for methyl-mercaptan.

Elemental Sulfur

As part of reducing SOx in FGT and SRU/TGUs, additional elemental sulfur is expected to be captured and sold as a commodity from Facilities A, C, D, E, F and G. Table 4-31 summarizes that additional sulfur that may be collected and sold as a result of implementing the proposed project. Some commercial uses of sulfur are primarily in manufacturing sulfuric acid, fertilizers, gunpowder, matches, insecticides and fungicides. However, because sulfur dust may form flammable or explosive mixtures with air, each of the affected facilities is currently equipped with sulfur pits that are specifically designed to handle this potential explosion hazard. The capacity of these existing sulfur pits is expected to be able to handle the additional increase in collected elemental sulfur.

Elemental sulfur is not a regulated substance pursuant to SCAQMD Rule 1401 or CalARP. The NFPA hazards ratings for elemental sulfur are as follows: health is rated 2 (moderately hazardous), flammability is rated 1 (slightly flammable) and reactivity is rated 0 (none). Therefore, the capture and sale of additional elemental sulfur is not expected in change the existing hazards setting at each affected facility.

Table 4-31
Amount of Potential Increase in Sulfur Sales

Facility ID	Affected Source Category	SOx Control Technology	Amount of Sulfur Collected (lbs/day)	Amount of Sulfur Collected (long tons/year)*
A	SRU/TGU	New Selective Oxidation Catalyst system	145.2	23.7
C	FGT	Convert all MEA absorbers to Sulfinol	40.4	6.6
D	FGT	Convert MEA and NaOH treatment of coker off-gas to Merox	67.5	11
E	FGT	Convert all DEA absorbers to Sulfinol	347.1	56.6
F	FGT	Add TG-10 to existing MDEA amine in the absorber	63.5	10.4
G	FGT	Convert MEA and NaOH treatment of coker off-gas to Merox	288.4	47
		TOTAL	**952.2**	**155.1**

* 1 long ton = 2,240 pounds

In conclusion, implementing the proposed project is expected to reduce SOx which will, in turn, reduce the hazardous component of SOx. Thus, based on the preceding analysis, the hazards and hazardous materials impacts from reducing SOx in flue gas exhaust streams are expected to be a benefit, and as such, less than significant for the proposed project.

Transportation Release

The transportation of hazardous materials can result in offsite releases through accidents or equipment failure. The proposed project is expected to increase the amount of NaOH, a hazardous material transported to or from the affected facilities. Refer to the "Caustic" discussion for this analysis.

Additional soda ash, catalyst and SOx reducing additives are expected to be delivered to some of the affected facilities, but no increase in transportation hazards is expected as none of these materials are considered to be hazardous. Further, limestone will be removed from an existing quarry on the property of Facility K and trucked within the location of the facility's boundaries, but no increase in transportation hazards is expected as limestone is not considered to be a hazardous substance

Lastly, additional amines (e.g., Sulfinol) may be delivered to some of the affected facilities causing the elimination or reduction of other amines (e.g., MEA and DEA) deliveries, but no increase in transportation hazards is expected as Sulfinol is considered to be less hazardous overall when compared to the existing amine deliveries.

Solid Waste

Each affected facility operator was asked to complete a survey about their solid waste and how it is currently handled. Table 4-32 summarizes the results of the survey. If the proposed project is implemented, additional solid waste may be generated. Tables 4-33 and 4-34 summarize the

increased amount of solid waste expected to be generated for implementation of Option 1 (i.e., if WGSs are installed) and Option 2 (i.e., if additional SOx reduction additives are used), respectively. In both cases, neither Option 1 nor Option 2 will result in the generation of solid hazardous waste.

Table 4-32
Current Amount of Solid Waste Generated

Facility ID	Current Amount of Solid Waste Generated (tons/day)	Type of Solid Waste	Is Solid Waste Hazardous?	Solid Waste is trucked to:
A	1.12	Catalyst Fines	NO	Cement Plant for Recycling
B	4.66	Catalyst Fines	NO	1. Cement Plant for Recycling; or, 2. Class III landfill for disposal as non- hazardous waste

Sensitive Receptors

None of the affected units operating at the existing facilities that may be altered by the proposed project are located within 1,000 feet or one-quarter mile of a sensitive receptor, including individuals at hospitals, nursing facilities, daycare centers, schools, and elderly intensive care facilities, as well as residential and off-site occupational areas. Therefore, no adverse significant impacts from hazardous emissions onsite or the handling of acutely hazardous materials, substances and wastes on sensitive receptors is expected from the proposed project.

Summary

Table 4-35 summarizes the substances that may be involved in the various processes at the affected facilities. Some of the substances listed are considered hazardous while others are not. Of the substances listed in Table 4-35, the only net increase in the use of a hazardous material will be for NaOH and the effects of this potential increase has been previously analyzed in the "Caustic" discussion. For the remaining substances identified, there will be either a decrease in use or no change from the existing setting. Thus, none of the changes to the existing setting is expected to result in a significant adverse impact for hazards and hazardous materials.

Table 4-35
Substances that May Be Affected By The Proposed Project

Substance	Potential Overall Increase, Decrease, or No Change from Existing Setting?	Contains TAC(s) per SCAQMD Rule 1401?	Hazardous per CalARP?	NFPA Rating: Health (Blue)	NFPA Rating: Flammability (Red)	NFPA Rating: Reactivity (Yellow)	NFPA Rating: Special (White)

SO2	Decrease	No	Yes	3	0	0	None
SO3	Decrease	Yes, cancer/ chronic & acute (pending)	Yes	3	0	2	None

NFPA Hazard Code Key: 4 = Extreme; 3 = High; 2 = Moderate; 1 = Slight; 0 = Insignificant; N/A = NFPA hazard is not assigned.

Project-Specific Impacts – Conclusion: Based on the preceding description of hazards and hazardous materials impacts, the proposed project is expected to generate less than significant adverse impacts related to any of the substances listed in Table 4-35. The analysis of hazard impacts has relied on information from past similar projects (i.e., installing new, or retrofitting

existing equipment to comply with SCAQMD rules and regulations and installation of associated NaOH storage tanks) where the SCAQMD was the lead agency responsible for preparing an environmental analysis pursuant to CEQA. To the extent that future projects to install new or modify existing SOx controls conform with the hazard analysis in this PEA, no further hazard analysis may be necessary. However, if site-specific characteristics are involved with future projects that are outside the scope of this analysis, further hazards analysis may be warranted.

Project-Specific Mitigation: Less than significant adverse impacts associated with hazards and hazardous materials are expected from the proposed project during both construction and operation, so no mitigation measures are required.

Level of Significance After Mitigation: The analysis concluded that the hazards and hazardous materials impacts from implementing the proposed project are considered to be adverse, but less than significant. Therefore, mitigation measures are not required.

Cumulative Hazards and Hazardous Materials Impacts: Because the project-specific hazards and hazardous materials impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative hazards and hazardous materials impacts.

Cumulative Mitigation Measures: None required.

HYDROLOGY AND WATER QUALITY IMPACTS

Significance Criteria

Potential impacts on water resources will be considered significant if any of the following criteria apply:

Water Demand:

- The existing water supply does not have the capacity to meet the increased demands of the project, or the project would use a substantial amount of potable water. For the purposes of this analysis, substantial amount of potable water demand is defined as the amount of water necessary to supply 500 dwelling units or approximately 133,911 to 223,186 gallons of potable water per day.
- The project increases demand for water by more than five million gallons per day.

Water Quality:

- The project will cause degradation or depletion of groundwater resources substantially affecting current or future uses.
- The project will cause the degradation of surface water substantially affecting current or future uses.
- The project will result in a violation of National Pollutant Discharge Elimination System (NPDES) permit requirements.
- The capacities of existing or proposed wastewater treatment facilities and the sanitary sewer system are not sufficient to meet the needs of the project.
- The project results in substantial increases in the area of impervious surfaces, such that interference with groundwater recharge efforts occurs.

- The project results in alterations to the course or flow of floodwaters.

Project-Specific Construction Impacts

Construction Background

Implementation of the proposed project is expected to result in construction activities associated with installing new or modifying existing SOx control equipment at the affected facilities, which are complex, well-established and mostly paved, industrial facilities. Depending on the proposed location within each facility's boundaries for the siting of any new control equipment that may be installed as a result of implementing the proposed project, construction activities such as digging, earthmoving, grading, slab pouring, or paving could occur if the proposed site for the new equipment is not suitable in its present form (e.g., graded with a foundation slab). Tables 4-36 and 4-37 contain a summary of the estimates of plot space needed per facility for Option 1 and Option 2 of the proposed project.

Based on the consultant's surveys of the affected facilities, if all affected facilities conduct site preparation activities, the total amount of disturbed area for all of the facilities combined is estimated to be 48,126 square feet (1.1 acres) for Option 1 and 40,976 square feet (0.9 acre) for Option 2. However, even if all affected facilities intend to conduct site preparation, not much overlap of site preparation activities would be expected since there are several years between the proposed rule amendment date (2010) and the proposed compliance date (January 1, 2019) and because the plot spaces are relatively small. Further, depending on the scale, site preparation typically can take anywhere from two weeks to one month. Therefore, it is unlikely that all affected facilities will do site preparation both in the same month of the same year. The largest parcel of land to be potentially disturbed at any one facility for both Options 1 and 2 of the proposed project could occur at Facility D and is approximately 11,930 square feet which represents approximately 25 percent of the total area to be disturbed for Option 1 and 29 percent of the total area to be disturbed for Option 2. On average, 4,384 square feet may be disturbed per facility under Option 2 and 3,725 square feet may be disturbed per facility under Option 2. Consistent with the assumption that, as a worst-case, up to four facilities could conduct overlapping site preparation activities, then the potential peak area that could be disturbed at any one time would be 33,836 square feet under Option 1 and 31,836 square feet under Option 2.

Under either option, the amount of area to be disturbed is relatively small such that one backhoe should be sufficient for site preparation activities. Since one backhoe can trench approximately 0.1 acre per day or 4,356 square feet per day, earthmoving activities at Facility D would take approximately three days under either Option 1 or Option 2. Even if four facilities conduct overlapping site preparation, earthmoving activities would take about the same amount of time since each plot space is relatively small (i.e., a ¼-acre plot or smaller) and there would be one backhoe in operation at each of the four facilities.

Construction Water Demand

To comply with the dust suppression requirements in SCAQMD Rule 403 – Fugitive Dust, during site preparation activities, some water is expected to be used. For example, one water truck per affected facility may be needed for dust suppression activities during the initial site preparation/earth moving portion of the proposed project. One water truck can hold approximately 6,000 gallons for dust control and it can be refilled over the course of the day if more than 6,000 gallons is needed. By applying one gallon of water per square foot of disturbed area, at a minimum of two times per day as required to minimize fugitive dust, the total amount of water expected to be used for dust suppression is approximately 8,712 gallons per facility per day. However, if four facilities conduct overlapping watering, then the maximum amount of water that could be used for site preparation is 34,848 gallons per day. On windy days, it may be necessary to conduct a third water application. Thus, the total peak amount of water that could be used for dust suppression is approximately 13,068 gallons per facility per day. Again, if four

facilities conduct overlapping watering, at a watering rate of three applications per day, then the peak amount of water that could be used for site preparation is 52,272 gallons per day.

Due to the need to quickly construct a proper foundation for the proposed control equipment, earth moving activities during site preparation are expected to be of a short duration lasting from two to three days to no longer than one month per facility. As such, the corresponding dust control activities are also not expected to last longer than one month per facility. Further, water used for dust suppression does not have to be of potable quality, but can be recycled water. Recycled water is currently available at three of the affected facilities and non-potable industrial-use groundwater is currently available at one additional facility. Additional recycled water availability is expected to expand to five other facilities by Summer 2013[82].

Since the earliest year when construction activities could begin would be in 2012, nine facilities are expected to have access to recycled or industrial-use groundwater for use during site preparation. There are three facilities (Facilities G, H and I) that do not currently have access to recycled or industrial-use groundwater and are not expected to have future access in 2012 or later. However, the amount of site preparation that would need to occur at these two facilities is expected to be about 7,840 square feet which would require approximately 15,680 gallons of water (at a watering rate of twice each day) to 23,520 gallons of water (at a watering rate of three times each day) for dust suppression activities during windy days.

Table 4-38 identifies the current water suppliers, the type of water currently supplied to each affected facility, and whether the facility currently buys recycled water. When surveyed, all of the responses from the affected facilities indicated that there is no limit to how much potable water they can purchase. Three facilities currently have pipeline access to and purchase recycled water and one facility has recycled water trucked in.

Table 4-39 identifies whether the affected facilities will have future access to recycled water pursuant to the LADWP's HRRWPP project. In addition to the three facilities that already have pipeline access to and purchase recycled water, the LADWP and WBMWD, as part of the HRRWPP project, are currently working with four facilities that would be affected by the proposed project to reach an agreement that would also have them start using recycled water. Staff at both the LADWP and WBMWD is working cooperatively to negotiate with these facilities to craft a Memorandum of Understanding that would encourage the installation of the necessary water conveyance infrastructure along with attractive pricing subsidies to access and maximize the use of recycled water while minimizing groundwater pumping and imported water use in oil refinery operations. Negotiations to supply recycled water to facilities affected by the proposed project are independent of, and do not rely on the proposed amendments to Regulation XX.

There are four facilities (G, H, I and K) identified in Table 4-39 that would not be able to have future or increased access to recycled water but only three facilities would be expected to

[82] Future access to recycled water for these five facilities is dependent upon the completion of the Harbor Refineries Recycled Water Pipeline Project (HRRWPP) by Summer 2013 (SCH No. 2008121093, certified on October 20, 2009). The HRRWPP will conserve potable water and instead produce and convey recycled water to multiple industrial and irrigation customers in the Los Angeles Harbor area (http://www.ladwp.com/ladwp/cms/ladwp011486.jsp). Proponents of the HRRWPP are working with each of the affected facilities to negotiate construction of a new water conveyance at their site in order to tie-into the recycled water pipeline.

continue to rely on potable water (G, H and I) during construction of the proposed project. Though the water used is not recycled, Facility K has access to non-potable industrial-use groundwater from their owner-operated groundwater wells and therefore, would not be expected to increase its existing use of potable water during construction of the proposed project.

Table 4-38
Current Water Supply Sources and Baseline Water Use at Affected Facilities

Facility ID	Purchases Potable Water From?	Potable Water Baseline (MMgal/day)	Pumps from Groundwater Wells?	Groundwater Pumping Baseline (MMgal/day)	Purchases Recycled Water From?	Recycled Water Use Baseline (MMgal/day)	Total Baseline Water Use[1] (MMgal/day)

J	CWS via WBMWD	Yes (non-potable)	Yes, new access via WBMWD by Summer 2013
K	Riverside Highland Water Co	Yes (non-potable)	No

Instead of installing new equipment, there are a few facility operators that may choose to modify or upgrade their existing SOx control equipment. In these cases, site preparation activities are not expected because the existing foundation and the existing equipment are expected to be reused in their current location and current plot space. Therefore, no water for dust suppression purposes is expected to be needed for any construction upgrades to existing SOx control equipment.

Once constructed, but prior to operation, additional water is expected to be used to hydrostatically (pressure) test all vessels and pipelines to ensure each structure's integrity and wastewater may be created during the testing. Pressure testing is typically a one-time event, unless a leak is found. Similar to dust suppression, water used for pressure testing does not have to be of potable quality, but can be recycled water.

Even though the potential increase in water use for both Option 1 and Option 2 of the proposed project is below the SCAQMD's five million gallons per day significance threshold for total water, it may be helpful to consider other criteria for evaluating what would be considered a substantial use of potable water, especially since California is in a State of Emergency for Drought. For example, CEQA Guidelines §15155 – City or County Consultation With Water Agencies, defines a "water demand" project in several ways. While the criteria for defining water demand are not significance thresholds per se, the criteria can provide some insight as to how city or county lead agencies evaluate water demand impacts. Most of the criteria in this part

of the CEQA Guidelines do not have a numerical criterion or direct methodology to correlate the criteria in terms of gallons per day for use as a significance threshold specific to potable water use. However, CEQA Guidelines §15155 (a)(1)(G) defines a water demand project as: "A project that would demand an amount of water equivalent to, or greater than, the amount of water required by a 500 dwelling unit project." To estimate what this means in terms of quantifying how much potable water could be used by a 500 dwelling unit (DU) project, the California Department of Water resources relies on a conversion factor range of 0.3 to 0.5 acre-feet of potable water per year per DU as shown in the following calculation[83]:

$$(500\ \text{DUs}) \times \frac{(0.3 - 0.5\ \text{acre-feet/year})}{(1\ \text{DU})} \times \frac{(325{,}851\ \text{gallons})}{(1\ \text{acre-foot})} \times \frac{(1\ \text{year})}{(365\ \text{days})} = 133{,}911\ \text{gallons/day to } 223{,}186\ \text{gallons/day}$$

Thus, the amount of water that would be needed during construction for dust suppression and pressure testing activities: 1) would not be considered a substantial use of potable water since several facilities are currently using or will have future access to recycled water; and 2) is less than the overall water demand significance threshold of five million gallons per day. Further, watering activities for dust suppression and pressure-testing are temporary and occur on a short-term basis. For these reasons, less than significant water demand/water use impacts are expected during construction of the proposed project.

Construction Water Quality

Any wastewater generated from pressure testing is expected to flow to each affected facility's wastewater treatment or collection system and recycled or discharged after treatment with process wastewater. Thus, wastewater generation from pressure testing activities is not expected to affect groundwater quality. Further, the volume of wastewater that will be generated from pressure testing is expected to be minimal and within the capacity of each facility's wastewater treatment and collection systems.

Further, because the total amount of disturbed area for all of the facilities combined is estimated to be 48,126 square feet (1.1 acres) for Option 1 and 40,976 square feet (0.9 acre) for Option 2 with the peak amount of area to be disturbed at Facility D at 11,930 square feet, the proposed construction activities will disturb less than 0.25 acre under Option 1 and 0.29 acre under Option 2 at each of the remaining facilities. This means that a NPDES General Permit for Storm Water Discharges Associated with Construction Activity, also referred to as a Storm Water Construction Permit, would not be required for any of the affected facilities. Because the proposed project is expected to disturb substantially less than one acre per facility, on-site collection of storm water in each facility's storm water collection system is expected to be about the same as the amount currently collected. Therefore, no significant impacts are expected from storm water during construction.

Construction Conclusion

In summary, less than significant adverse water demand and wastewater impacts are expected during construction of the proposed project.

[83] Draft Guidebook for Implementation of Senate Bill 610 and Senate Bill 221 of 2001 to assist water suppliers, cities, and counties in integrating water and land use planning, California Department of Water Resources, September 2002, p.3

Project-Specific Operation Impacts

Operation Background

Facilities affected by the proposed project are expected to install new or modify their existing air pollution control equipment in order to comply with the proposed project. Additional water demand and wastewater generation are expected to result from the operation of most of the proposed control technologies. Table 4-40 identifies the proposed control technologies that use water and generate wastewater during operations for Options 1 and 2 of the proposed project, respectively. The majority of the proposed SOx control technologies listed in these tables utilizes water and generates wastewater. It is important to note that the quality of water that may be used in the various SOx control technologies does not have to be potable as recycled or industrial-use groundwater can be utilized instead.

Table 4-40
Proposed Control Technologies and Their Corresponding
Potential Operational Water Use and Wastewater Generation

Main Equipment	Proposed Control Technology	Proposed Control Technology Uses Water?	Proposed Control Technology Generates Wastewater?
FCCU	WGS	Yes	Yes
FCCU	SOx Reducing Catalyst	No	No
SRU/TGU	WGS	Yes	Yes
SRU/TGU	Selective Oxidation Catalyst	No	No
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	Yes	Yes
Refinery Boilers/Heaters	FGT (Additive to Existing Amine System)	No	No
Coke Calciner	WGS	Yes	Yes
Glass Melting Furnaces	WGS	Yes	Yes
Sulfuric Acid Mfg.	WGS	Yes	Yes
Sulfuric Acid Mfg.	Upgrade Existing Cansolv Unit	Yes	No[1]
Cement Kilns	DGS	Yes	No[2]

[1] More water (as steam) is required to complete the upgrade. However, the steam is evaporated during the process so there is no wastewater stream generated.

[2] All of the injected water is evaporated during the process so there is no wastewater stream generated.

Tables 4-41 and 4-42 quantify the potential increases in operational water use and wastewater generation as a result of installing new or upgrading existing SOx controls to comply with Options 1 and 2 of the proposed project, respectively. If all of the proposed control technologies are installed or upgraded, the potential increase in water use is estimated to be approximately 0.88 MMgal/day under Option 1 and 0.64 MMgal/day under Option 2. Further, if all of the proposed control technologies are installed or upgraded, the potential increase in wastewater generated would be approximately 0.27 MMgal/day under Option 1 and 0.16 MMgal/day under

Option 2. Hydrology and water quality impacts from the proposed project are discussed in detail in the following sections.

Table 4-41
Option 1: Potential Increases in Operational Water Demand and Wastewater Generation

Main Equipment	Proposed Control Technology	No. of Facilities to Install or Upgrade Controls	No. of Units Expected to Be Installed or Upgraded	Potential Increase in Operational Water Demand (gal/day)	Potential Increase in Wastewater Generation (gal/day)
FCCU	WGS	4	4	241,096	112,329
SRU/TGU	WGS	2	3	354,247	70,959
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	5	5	52,055	46,575
Coke Calciner	WGS	1	1	40,896	16,992
Glass Melting Furnaces	WGS	1	2	58,464	12,877
Sulfuric Acid	WGS	1	1	19,589	10,800
Sulfuric Acid	Upgrade Existing Cansolv Unit	1	1	6,336	0[1]
Cement Kilns	DGS	1	2	110,685	0[2]
		Total	**19**	**883,368**	**270,532**

[1] More water (as steam) is required to complete the upgrade. However, the steam is evaporated during the process so there is no wastewater stream generated.

[2] All of the injected water is evaporated during the process so there is no wastewater stream generated.

Table 4-42
Option 2: Potential Increases in Operational Water Demand and Wastewater Generation

Main Equipment	Proposed Control Technology	No. of Facilities to Install or Upgrade Controls	No. of Units Expected to Be Installed or Upgraded	Potential Increase in Operational Water Demand (gal/day)	Potential Increase in Wastewater Generation (gal/day)
FCCU	SOx Reducing Catalyst	5	5	0	0

Cement Kilns	DGS	1	2	110,685	0[2]
		Total	**19**	**642,272**	**158,203**

[1] More water (as steam) is required to complete the upgrade. However, the steam is evaporated during the process so there is no wastewater stream generated.

[2] All of the injected water is evaporated during the process so there is no wastewater stream generated.

Water Demand

As summarized in Tables 4-43 and 4-44, each affected facility provided its water demand baseline and these water usage rates were compared to each facility's estimated potential increase in water demand that may result from implementing Option 1 or Option 2 of the proposed project. For both Option 1 and Option 2, the peak percentage increase from baseline levels when compared to the proposed project was approximately 45 percent (Facility I) but most of the affected facilities have a potential increase in water demand from one to four percent above each facility's baseline. The overall increase in water demand for Option 1 is 1.53 percent above the total water use baseline for all of the affected facilities combined. Similarly, the overall increase in water demand for Option 2 is 1.11 percent above the total water use baseline for all of the affected facilities combined.

Table 4-43
Option 1: Potential Increases in Operational Water Demand per Facility

To have a better understanding about the availability of water and the source (i.e., potable versus non-potable recycled or industrial-use groundwater), SCAQMD staff contacted each supplier of water used for industrial applications for each of the affected facilities[84], and all of the suppliers indicated that they would be able to accommodate the additional operational water demand if the proposed project goes forward. In addition, each water supplier specified whether the additional water to be supplied will be recycled water or potable water. In the case of recycled water, the water supplier indicated whether the recycled water is currently available or whether it would be available in the future pursuant to the aforementioned HRRWPP project.

As part of making the determination if water supplies will be sufficient for the proposed project, the availability of recycled or industrial-use groundwater is an important factor. Seven facilities are expected to have either increased access (e.g., Facilities A, B and D) or new future access (e.g., Facilities C, E, F and J) to recycled water upon completion of the HRRWPP[85]. The

[84] Facility K is the only facility that does not purchase water for its industrial operations; instead, the industrial-use water (non-potable) is supplied by the facility-owned wells.

[85] The future availability of recycled water applies to certain facilities that do not currently have access to obtain recycled water for their processes but that will have access after completion of the LADWP's HRRWPP project (certified on October 20, 2009) by Summer 2013 (http://www.ladwp.com/ladwp/cms/ladwp011486.jsp). In addition, future access to recycled water is contingent upon each facility within the HRRWPP project area constructing a new water conveyance at their site in order to tie-into the recycled water pipeline.

HRRWPP is a project shared by the LADWP and WBMWD to conserve potable water and instead produce and convey recycled water to multiple industrial and irrigation customers in the Los Angeles Harbor area. Construction of the HRRWPP began on October 26, 2009 and is estimated to be completed by Summer 2013. However, even if the pipeline and meter is installed, these facilities will need to make modifications to handle the potential increase in recycled water or install the water conveyance infrastructure piping to tie-in to the recycled water pipeline.

Tables 4-45 and 4-46 identify the amount and availability status of using non-potable[86] and potable water to supply the potential increased water use as a result of Option 1 and Option 2 of the proposed project, respectively. The amount of non-potable water that can currently be used under Option 1 of the proposed project is 681,781 gallons per day plus the future availability of non-potable water (to be available beginning Summer 2013) of 102,227 gallons per day for a total of 784,008 gallons per day. Of the proposed increase of total water at 883,368 gallons per day under Option 1, 89 percent may be supplied by recycled or non-potable groundwater. The remaining amount of increased potential water demand under Option 1 of the proposed project is estimated to be 11 percent or 99,360 gallons per day and is expected to be satisfied by potable water.

Similarly, the amount of non-potable water that can currently be used under Option 2 of the proposed project is 533,836 gallons per day plus the future availability of non-potable water (to be available beginning Summer 2013) is 9,076 gallons per day for a total of 542,912 gallons per day. Of the proposed increase of total water at 642,272 gallons per day under Option 2, 84 percent may be supplied by recycled or non-potable groundwater. The remaining amount of increased potential water demand under Option 2 of the proposed project is estimated to be 16 percent or 99,360 gallons per day and is expected to be satisfied by potable water.

[86] Non-potable water can be either recycled water or industrial-use groundwater.

Table 4-45
Option 1: Potential Increases in Non-Potable and Potable Water Use

Main Equipment	Proposed Control Technology	Potentially Available Non-Potable Water Use		Potentially Available Potable Water Use (gal/day)	Total Potential Increase in Water Use (gal/day)
		Current [1] (gal/day)	Future[2] (gal/day)		
FCCU	WGS	147,945	93,151	0	241,096
SRU/TGU	WGS	354,247	0	0	354,247
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	49,315	2,740	0	52,055
Coke Calciner	WGS	0	0	40,896	40,896
Glass Melting Furnaces	WGS	0	0	58,464	58,464
Sulfuric Acid Mfg.	WGS	19,589	0	0	19,589
Sulfuric Acid Mfg.	Upgrade Existing Cansolv Unit	0	6,336	0	6,336
Cement Kilns	DGS	110,685	0	0	110,685
	Total	**681,781**	**102,227**	**99,360**	**883,368**

[1] The current availability of non-potable water values assumes that the facilities which currently obtain recycled or industrial-use groundwater for their processes will continue to do so if there is a need to increase water use as part of the proposed project.

[2] The future availability of non-potable water values applies to certain facilities that do not currently have access to obtain recycled or industrial-use groundwater for their processes but that will have access after completion of the LADWP's HRRWPP project by Summer 2013.

Table 4-46
Option 2: Potential Increases in Non-Potable and Potable Water Use

Main Equipment	Proposed Control Technology	Potentially Available Non-Potable Water Use		Potentially Available Potable Water Use (gal/day)	Total Potential Increase in Water Use (gal/day)
		Current [1] (gal/day)	Future[2] (gal/day)		
FCCU	SOx Reducing Additive	0		0	0
SRU/TGU	WGS	354,247	0	0	354,247
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	49,315	2,740	0	52,055
Coke Calciner	WGS	0	0	40,896	40,896
Glass Melting Furnaces	WGS	0	0	58,464	58,464
Sulfuric Acid	WGS	19,589	0	0	19,589
Sulfuric Acid	Upgrade Existing Cansolv Unit	0	6,336	0	6,336
Cement Kilns	DGS	110,685	0	0	110,685
	Total	**533,836**	**9,076**	**99,360**	**642,272**

[1] The current availability of non-potable water values assumes that the facilities which currently obtain recycled or industrial-use groundwater for their processes will continue to do so if there is a need to increase water use as part of the proposed project.

[2] The future availability of non-potable water values applies to certain facilities that do not currently have access to obtain recycled or industrial-use groundwater for their processes but that will have access after completion of the LADWP's HRRWPP project by Summer 2013.

Table 4-47 summarizes the projected increases of potable water, recycled water (both current and projected future availability) and industrial-use groundwater that is estimated to implement both Option 1 and Option 2 of the proposed project at the affected facilities.

Table 4-47
Distribution of Projected Water Demand by Water Type

	Option 1		Option 2	
Type of Water	**Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**	**Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**
Potable	99,360	11%	99,360	16%
Recycled (non-potable)	659,624	75%	418,528	65%
Industrial-Use Groundwater (non-potable)	124,384	14%	124,384	19%
TOTAL	**883,368**	**100%**	**642,272**	**100%**

Option 1 of the proposed project has been shown to potentially increase total water demand by approximately 883,368 gallons per day and 11 percent or 99,360 gallons per day of the total water demand would need to be supplied by potable water if all projected recycled water becomes available. Similarly, Option 2 of the proposed project has been shown to potentially increase total water demand by approximately 642,272 gallons per day and 16 percent or 99,360 gallons per day of the total water demand would need to be supplied by potable water.

Thus, the amount of water that would qualify as a water demand project can be adjusted to separate the potable water from the current and future uses of recycled water and industrial-use groundwater needed for the proposed project. Thus, to establish whether the proposed project qualifies as a water demand project, the potential increase in water use can be interpreted to mean the potential increase of potable water only (in this case, 99,360 gallons per day for both Option 1 and Option 2). Since the projected increase of potable water would be less than the estimated range of water that would be needed for a 500 DU project (e.g., 133,911 to 223,186 gallons per day), neither Option 1 nor Option 2 of the proposed project would qualify as a water demand project.

However, the projections for new or increased future access to recycled water are 102,227 gallons per day under Option 1 and 9,076 gallons per day under Option 2 and the availability of future access to recycled water is not guaranteed. In the event that the future access to recycled water does not occur as planned by Summer 2013 in accordance with the HRRWPP, the potential increase in potable water needed for the proposed project would need to be adjusted to include the amount of future recycled water. As such, the amount of potable water demand could increase to 201,587 gallons per day under Option 1 and 108,436 gallons per day under Option 2. In the event that future access to recycled water does not occur as planned, the distribution between potable and recycled water demand shifts as summarized in Table 4-48.

Table 4-48
Adjusted Distribution of Projected Water Demand by Water Type if Future Supplies of Recycled Water Are Not Available

	Option 1		Option 2	
Type of Water	**Adjusted Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**	**Adjusted Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**
Potable	201,587	23%	108,436	17%
Recycled (non-potable)	557,397	63%	409,452	64%
Industrial-Use Groundwater (non-potable)	124,384	14%	124,384	19%
TOTAL	**883,368**	**100%**	**642,272**	**100%**

The adjusted estimate for increased potable water demand under Option 1 at 201,587 gallons per day is within the range between 133,911 gallons per day and 223,186 gallons per day based on the 500 DU water demand calculations. By applying the 500 DU water demand criteria to use as a significance threshold for potable water demand, Option 1 of the proposed project may qualify as a water demand project and thus, may result in significant adverse water demand impacts.

However, under Option 2, the adjusted estimate for increased potable water demand would be 102,227 gallons per day, which is below the minimum amount of potable water needed to qualify for as a water demand project per the 500 DU calculations (e.g., 133,911 gallons per day). Thus, for this reason, Option 2 of the proposed project is expected to contribute to less than significant adverse water demand impacts.

Lastly, to investigate whether the existing water supply has the capacity to meet the increased water demand of the proposed project, SCAQMD staff has been coordinating with various water suppliers (e.g., LADWP, MWD, WBMWD, Long Beach Water Department, City of Vernon etc.) to the affected facilities. Water suppliers for all of the facilities that either currently use recycled water or are expected to have future use of recycled water have indicated that there will be sufficient supply of recycled water for the proposed project. In addition, the water suppliers for Facilities G, H and I have indicated that they can supply the estimated additional potable water needed for operating WGSs. Lastly, Facility K operates its own groundwater wells to pump non-potable industrial-use groundwater for their day-to-day operations. Because Facility K's groundwater pumping permit does not limit the amount of water that can be pumped from the wells, any additional water needed to implement the proposed project is expected to be available.

Water Quality

As summarized in Tables 4-49 and 4-50, each affected facility provided their wastewater discharge limits and these limits were compared to each facility's estimated potential increase in wastewater that may result from implementing Option 1 and Option 2 of the proposed project, respectively. The peak percentage increase from baseline levels when compared to the proposed project was approximately 12 percent (Facility F) under Option 1 and nine percent (Facility H) under Option 2. An increase of 25 percent would trigger a permit revision and would be considered a significant adverse wastewater impact. Since all of the affected facilities have been shown under both options of the proposed project to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated as

a result of the proposed project. Thus, the operational impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant.

Changes to each affected facility's storm water collection systems are expected to be less than significant since most of the changes will occur within existing units (i.e., installing control equipment on existing equipment or upgrading existing control equipment). Further, typically most of the areas likely to be affected by the proposed project are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each facility's current wastewater collection or treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions.

The proposed project is expected to involve construction activities located within the confines of existing facilities and does not include the construction of any new housing so it would not place new housing within a 100-year flood hazard area. It is likely that most affected facilities are not located within a 100-year flood hazard area. Any affected facilities that may be located in a 100-year flood area could impede or redirect 100-year flood flows, but this would be considered part of the existing setting and not an effect of the proposed project. The proposed project would not require locating new facilities within a flood zone, so it is not expected to expose people or property to any known water-related flood hazards.

[1] Wastewater limits were obtained from each facility's wastewater permit(s). For any facility that has multiple discharge limits (i.e. dry weather, wet weather, etc.), the most conservative limit will be used for the purposes of this comparison.

The proposed project does not require construction of new facilities in areas that could be affected by tsunamis. Of the facilities affected by the proposed project, some are located near the Ports of Long Beach and Los Angeles. However, the port areas are protected from tsunamis by the construction of breakwaters. Construction of breakwaters combined with the distance of each facility from the water is expected to minimize the potential impacts of a tsunami or seiche so that no significant impacts are expected. The proposed project does not require construction of facilities in areas that are susceptible to mudflows (e.g., hillside or slope areas). Existing affected facilities that are currently located on hillsides or slope areas may be susceptible to

mudflow, but this would be considered part of the existing setting. As a result, the proposed project is not expected to generate significant adverse mudflow impacts.

Lastly, the proposed project is not expected to significantly adversely affect the quantity or quality of groundwater in the area of each affected facility. No significant adverse impacts to groundwater quality are expected from the proposed project because: 1) wastewater will continue to be collected and treated in each of the affected facility's wastewater treatment systems or in compliance with the current wastewater discharge permits, as applicable; 2) no underground storage tanks are expected to be constructed as part of the proposed project; 3) containment berms will be required or may already exist around the new or modified units to minimize the potential for spills to contaminate soil and groundwater; and, 4) any new storage tanks that may be proposed will be required to comply with BACT and other safety requirements such as double bottom and monitoring requirements.

Water Demand and Water Quality Conclusion

The water demand impacts that may result from the proposed project have been shown to require approximately 883,368 gallons per day of total water under Option 1 of the proposed project and 642,272 gallons per day of total water under Option 2 of the proposed project. Under Option 1 of the proposed project, approximately 75 percent of the total water demand is expected to be satisfied with current and future supplies of recycled water, 14 percent is expected to be supplied by industrial-use groundwater, and the remaining 11 percent is expected to be supplied by potable water. However, if future access to recycled water does not occur, then approximately 63 percent of the total water demand is expected to be satisfied with current supplies of recycled water, 14 percent is expected to be supplied by industrial-use groundwater, and the remaining 23 percent is expected to be supplied by potable water under Option 1.

Similarly under Option 2 of the proposed project, approximately 65 percent of the total water demand is expected to be satisfied with current and future supplies of recycled water, 19 percent is expected to be supplied by industrial-use groundwater, and the remaining 16 percent is expected to be supplied by potable water. Again, if future access to recycled water does not occur, then approximately 63 percent of the total water demand is expected to be satisfied with current supplies of recycled water, 14 percent is expected to be supplied by industrial-use groundwater, and the remaining 17 percent is expected to be supplied by potable water under Option 2.

Based on the preceding analysis, neither Option 1 nor Option 2 of the proposed project is expected to exceed SCAQMD's significance threshold of five million gallons of total water per day. If future supplies of recycled water become available, neither Option 1 nor Option 2 of the proposed project is expected to require a substantial amount of potable water as calculated pursuant to the water demand project criteria. However, in the event that future supplies of recycled water do not become available, only the potable water demand under Option 1 may require a substantial amount of potable water as calculated pursuant to the water demand project criteria. Further, the water suppliers have indicated that there will be an adequate supply of water (current and future supplies of recycled water plus potable water) for the proposed project under both Option 1 and Option 2. Therefore, the water demand impacts are concluded to be significant under Option 1 and less than significant under Option 2.

Lastly, based on the aforementioned considerations, the potential groundwater, wastewater discharge and storm water discharge impacts that may result from both Option 1 and Option 2 of the proposed project are expected to be less than significant.

Project-Specific Mitigation: Significant adverse impacts associated with water demand under Option 1 are expected from the proposed project during operation. However, for any facility that installs a WGS as part of the proposed project under either Option 1 or Option 2, SCAQMD staff requires that the facility operators utilize both current supplies and future supplies of recycled water in accordance with the California Water Code, and if available, pursuant to the HRRWPP Project, for operation of a WGS.

Based on the preceding discussion, the following mitigation measures will apply to the proposed project:

HWQ-1 When SOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the SOx control equipment.

HWQ-2 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the SOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be supplied to the project.

Level of Significance After Mitigation: The analysis shows that proposed increase in total water use under both Option 1 and Option 2 cannot be fully supplied with recycled water (either currently or in the future) and non-potable groundwater and that some potable water may still be required for certain facilities. While the potentially adverse water impacts can be reduced to below significance if facility operators are required to use current and future supplies of recycled water, if available, there is no absolute guarantee at the time of this writing that future supplies of recycled water will be available to the affected facilities included in the HRRWPP Project. While the use of recycled water can help substantially reduce the water demand impacts, the overall water demand will not be completely mitigated. Therefore, the proposed project will remain significant after mitigation for water demand.

The analysis also concluded that the water quality impacts from implementing the proposed project are considered to be adverse, but not significant.

Cumulative Hydrology and Water Quality Impacts: Because the project-specific water demand impacts under Option 1 have been concluded to be significant due to the 500 DU potable water demand criteria and in consideration of California's on-going drought and that 100 percent of the potential increase in water use cannot be supplied by recycled water, it could be argued that the proposed project is cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1). Therefore, the proposed project is expected to generate significant adverse cumulative water demand impacts.

However, because the project-specific water quality impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to

CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative water quality impacts.

Cumulative Mitigation Measures: The potentially adverse water impacts can be reduced further than initial estimates if recycled water is employed for WGS installations. Even with the use of recycled water as part of the implementing the proposed project, the analysis shows that 100 percent of the proposed increase in total water demand cannot be fully offset by the use of recycled water. While the use of recycled water can help substantially reduce the water demand impacts, the overall total water demand will not be completely mitigated. Therefore, the proposed project will remain cumulatively significant after mitigation for water demand.

With regard to water quality impacts, because the proposed project is not expected to generate significant adverse cumulative water quality impacts, no cumulative water quality mitigation measures are required.

TRANSPORTATION/TRAFFIC

Significance Criteria

Impacts on transportation/traffic will be considered significant if any of the following criteria apply:

- Peak period levels on major arterials are disrupted to a point where the LOS is reduced to D, E or F for more than one month.
- An intersection's volume to capacity ratio increase by 0.02 (two percent) or more when the LOS is already D, E or F.
- A major roadway is closed to all through traffic, and no alternate route is available.
- There is an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system.
- The demand for parking facilities is substantially increased.
- Water borne, rail car or air traffic is substantially altered.
- Traffic hazards to motor vehicles, bicyclists or pedestrians are substantially increased.
- The need for more than 350 permanent employees during operation.
- An increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day during operation
- Increase customer traffic by more than 700 visits per day during operation.

Construction activities resulting from implementing the proposed project may generate a slight, albeit temporary, increase in traffic in the areas of each affected facility associated with construction workers, construction equipment, and the delivery of construction materials. However, the proposed project is not expected to cause a significant increase in traffic relative to the existing traffic load and capacity of the street systems surrounding the affected facilities. Also, the proposed project is not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during construction as explained in the following paragraph.

As previously noted in the section that discusses "Air Quality," the maximum construction workforce during any six-month construction period is expected to be approximately 175 workers per facility. For a worst-case analysis, four facilities which may need a total of up to 700 workers were assumed to undergo overlapping construction activities. Even if it is assumed

that all 700 construction workers drive alone (which represents an average vehicle ridership equal to 1.0) not all of the workers would be driving to the same facility. It is unlikely that these vehicle trips would substantially affect the LOS at any intersection because the trips will be somewhat dispersed over a large area and the workers would not all arrive at the site at the exact same time. Therefore, the work force at each affected facility is not expected to significantly increase as a result of the proposed project. Further, the conclusion of no significant transportation impacts based on the workforce is consistent with the transportation analyses in the CEQA documents prepared for six refineries in accordance with the CARB Phase III Reformulated Gasoline requirements[87]. Specifically, the number of construction workers for each of the six projects ranged from approximately 200 to 700 daily construction worker trips and each of these projects was concluded to have no significant transportation impacts.

The operation-related traffic will be primarily for deliveries of NaOH, SOx reducing additives, soda ash, limestone, ESx catalyst, TG-10 blend, Sulfinol, Merox catalyst, and elemental sulfur and for hauling away of solid waste to be recycled or disposed of in a Class III landfill. Table 4-51 contains a summary of the delivery and haul away distances and frequencies for each substance that is associated with the proposed project. Of the substances listed for deliveries, all but five are available from local suppliers within the District. For the local suppliers, a round-trip delivery distance of 50 miles was assumed. This distance is expected to be conservative as most suppliers are located closer to the affected facilities. However, suppliers for SOx Reducing Additives, ESx Catalyst, Merox Catalyst, TG-10 and Sulfinol are all located out of state. Thus, deliveries of these materials are assumed to be trucked into the District from out of state and the delivery mileage assumptions reflect the round-trip distance from the state line, either at the Arizona/California border (e.g., 400 miles) or the Nevada/California border (e.g., 500 miles). For solid waste disposal, facility operators will have three options: 1) disposal of solid waste in a landfill located within the District or recycling of solid waste at a cement plant located within the District (e.g., 162 round-trip miles); 2) recycling of solid waste at a cement plant located outside of the District but within California (e.g., 264 round-trip miles); and, 3) recycling of solid waste at a cement plant located outside of the District and outside of California (e.g., 400 round-trip miles). For a worst-case analysis of solid waste disposal trips, the maximum mileage of 400 round-trip miles was assumed.

		TOTAL: OPTION 2	**30**	**8,076**	**275**	**108,318**

* A negative number means a reduction in trips and mileage driven.

The amount of peak daily truck trips associated with the proposed project is 33 for Option 1 and 30 for Option 2. Since neither option is expected to have an increase in heavy-duty transport

truck traffic to and/or from the facility by more than 350 truck round trips per day, less than significant transportation impacts are expected from implementation of the proposed project. Further, taking into consideration the "worst-case" delivery and hauling transportation schedule, delivery and hauling trips associated with the proposed project are not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during operations. Thus, the projected increase of traffic due to construction and operational activities is expected to be minimal and thus, the traffic impacts are expected to be less than significant for the proposed project.

Though some of the facilities that will be affected by the proposed project are located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, actions that would be taken to comply with the proposed project, such as installing new air pollution control equipment, are not expected to significantly influence or alter air traffic patterns. Further, the size and type of air pollution control devices that would be installed would not be expected to affect navigable air space because they would not be substantially taller than other equipment at affected facilities. Thus, the proposed project would not result in a change in air traffic patterns, an increase in traffic levels or a change in location that results in substantial safety risks.

The siting of each existing affected facility is consistent with surrounding land uses and traffic/circulation in the surrounding areas of the affected facilities. Thus, the proposed project is not expected to substantially increase traffic hazards or create incompatible uses at or adjacent to the affected facilities. Aside from the temporary effects due to a slight increase in truck traffic when facilities undergo construction activities, the proposed project is not expected to alter the existing long-term circulation patterns. The proposed project is not expected to require a modification to circulation, thus, no long-term impacts on the traffic circulation system are expected to occur. The proposed project does not involve construction of any roadways, so there would be no increase in roadway design feature that could increase traffic hazards. Emergency access at each affected facility is not expected to be impacted by the proposed project. Further, each affected facility is expected to continue to maintain its existing emergency access gates.

Each affected facility will be expected to provide parking for the construction workers, as applicable, either on or within close proximity to each facility. No additional parking will be needed after completion of the construction phase because the work force at each facility is not expected to significantly increase as a result of the proposed project.

Lastly, construction and operation activities resulting from the proposed project are not expected to conflict with policies supporting alternative transportation since the proposed project does not involve or affect alternative transportation modes (e.g., bicycles or buses) because the construction and operation activities related to the proposed project will occur solely in existing industrial, commercial, and institutional areas. Based upon these considerations, significant transportation/traffic impacts are not expected from the implementation of the proposed project.

Project-Specific Mitigation: No significant adverse impacts associated with transportation/traffic impacts are expected from the proposed project during construction or operation, so no mitigation measures are required.

Level of Significance After Mitigation: The analysis concluded that the transportation/traffic impacts from implementing the proposed project are considered to be adverse, but not significant. Therefore, mitigation measures are not required.

Cumulative Transportation/Traffic Impacts: Because the project-specific transportation/traffic impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative transportation/traffic impacts.

Cumulative Mitigation Measures: None required.

POTENTIAL ENVIRONMENTAL IMPACTS FOUND NOT TO BE SIGNIFICANT

While all the environmental topics required to be analyzed under CEQA were reviewed to determine if the proposed project would create significant impacts, the screening analysis concluded that the following environmental areas would not be significantly adversely affected by the proposed project: agriculture and forest resources, biological resources, cultural resources, geology/soils, land use and planning, mineral resources, noise, population and housing, public services, recreation, and solid/hazardous waste. One comment was received on the NOP/IS that disputed the conclusions of less than significant for the topics of Noise, Land Use, and Solid/Hazardous Waste. For the topics of Noise and Land Use, there was no supporting evidence to justify a conclusion of significance. Further, when compared to other CEQA documents prepared for projects with similar construction activities, the topics of Noise and Land Use were concluded to have less than significant effects. In addition, projected solid waste data obtained by the consultant from each affected facility indicated that the solid waste that may be generated by the proposed project is expected to be a commodity and is not expected to be disposed of in a landfill. Instead the solid waste will either be sent to a cement plant for recycling or re-used on site. In any case, even if the entire amount of solid waste generated was sent to a landfill, it would not exceed the capacity of the designated landfills. Refer to Appendix B for the solid waste data. Therefore, the solid/hazardous waste impacts that may result from implementing the proposed project are expected to be less than significant.

The following is a brief discussion of each topic found not to be significant in the NOP/IS.

Agriculture and Forest Resources

All construction and operational activities that would occur as a result of implementing the proposed project are expected to occur within the confines of the existing affected facilities. The proposed project would be consistent with the industrial or heavy manufacturing zoning requirements for the various facilities and there are no agricultural or forest resources or operations on or near the affected facilities. No agricultural resources including Williamson Act contracts are located within or would be impacted by construction activities at the affected facilities. Therefore, the proposed project would not result in any new construction of buildings or other structures that would convert farmland to non-agricultural use or conflict with zoning for agricultural use or a Williamson Act contract.

The proposed project would also not result in any new construction of buildings or other structures that would cause the loss of forest land or conversion of forest land to non-forest use. Because there are no forestry resources or operations on or near the affected facilities, the proposed project would not conflict with existing zoning for, or cause rezoning of, forest land (as

defined in Public Resources Code §12220(g)), timberland (as defined by Public Resources Code §4526), or timberland zoned Timberland Production (as defined by Government Code §51104 (g).

Lastly, since the proposed project would not substantially change the facility or process for which the SOx control equipment are utilized, there are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments and no land use or planning requirements relative to agriculture and forest resources will be altered by the proposed project.

Therefore, for these aforementioned reasons, the proposed project is not expected to create significant adverse agriculture and forest resource impacts.

Biological Resources

The proposed project would only affect 14 units operating at 11 existing facilities located throughout the District. The physical changes involved that may occur focus on the installation of SOx control equipment such as WGSs, and DGSs as well as the use of selective oxidation catalyst or SOx reducing catalyst to reduce SOx emissions at the affected facilities. All of the affected units operating at existing facilities are located primarily in industrial areas, which have already been greatly disturbed. In general, these areas currently do not support riparian habitat, federally protected wetlands, or migratory corridors. Additionally, special status plants, animals, or natural communities are not expected to be found within close proximity to the affected facilities. Therefore, the proposed project would have no direct or indirect impacts that could adversely affect plant or animal species or the habitats on which they rely in the SCAQMD's jurisdiction. The current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions. A conclusion in the Final Program EIR for the 2007 AQMP was that population growth in the region would have greater adverse effects on plant species and wildlife dispersal or migration corridors in the basin than SCAQMD regulatory activities, (e.g., air quality control measures or regulations). The current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions.

Further, the proposed project is not envisioned to conflict with local policies or ordinances protecting biological resources or local, regional, or state conservation plans. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Additionally, the proposed project will not conflict with any adopted Habitat Conservation Plan, Natural Community Conservation Plan, or any other relevant habitat conservation plan, and would not create divisions in any existing communities because all activities associated with complying with the proposed project will occur at existing industrial facilities. Therefore, the proposed project is not expected to create significant adverse biological resource impacts.

Cultural Resources

There are existing laws in place that are designed to protect and mitigate potential impacts to cultural resources. Since construction-related activities associated with the implementation of the proposed project are expected to be confined within the existing footprint of the affected facilities, no impacts to historical resources are expected to occur as a result of implementing the proposed project.

Installing add-on controls and other associated equipment to comply with the proposed project may require disturbance of previously disturbed areas, i.e., existing industrial facilities. However, since construction-related activities are expected to be confined within the existing footprint of the affected facilities, the proposed project is not expected to require physical changes to the environment, which may disturb paleontological or archaeological resources. Furthermore, it is envisioned that these areas are already either devoid of significant cultural resources or whose cultural resources have been previously disturbed. Therefore, the proposed project has no potential to cause a substantial adverse change to a historical or archaeological resource, directly or indirectly destroy a unique paleontological resource or site or unique geologic feature, or disturb any human remains, including those interred outside a formal cemeteries. The proposed project is, therefore, not anticipated to result in any activities or promote any programs that could have a significant adverse impact on cultural resources in the District. The proposed project is, therefore, not anticipated to result in any activities or promote any programs that could have a significant adverse impact on cultural resources in the District.

Geology and Soils

Since the proposed project would result in construction activities in industrial settings to install SOx control equipment at the affected facilities, little site preparation is anticipated that could adversely affect geophysical conditions in the jurisdiction of the SCAQMD. Southern California is an area of known seismic activity. Since the proposed project would result in construction activities in industrial settings to install SOx control equipment, little site preparation is anticipated that could adversely affect geophysical conditions in the jurisdiction of the SCAQMD. Accordingly, the installation of add-on controls at existing affected facilities to comply with the proposed project is expected to conform with the Uniform Building Code and all other applicable state and local building codes. As part of the issuance of building permits, local jurisdictions are responsible for assuring that the Uniform Building Code is adhered to and can conduct inspections to ensure compliance. The Uniform Building Code is considered to be a standard safeguard against major structural failures and loss of life. The basic formulas used for the Uniform Building Code seismic design require determination of the seismic zone and site coefficient, which represents the foundation condition at the site. The Uniform Building Code requirements also consider liquefaction potential and establish stringent requirements for building foundations in areas potentially subject to liquefaction. Thus, the proposed project would not alter the exposure of people or property to geological hazards such as earthquakes, landslides, mudslides, ground failure, or other natural hazards. As a result, substantial exposure of people or structures to the risk of loss, injury, or death is not anticipated.

Since add-on controls will likely be installed at existing facilities, during construction of the proposed project, a slight possibility exists for temporary erosion resulting from excavating and grading activities, if required. These activities are expected to be minor since the existing facilities are generally flat and have previously been graded. Appendix B contains the air quality analysis estimating fugitive PM10 emissions from activities such as grading, trenching, stockpile loading, wind erosion, and truck filling and dumping in order to install SOx control equipment. Further, this analysis confirms that wind erosion is not expected to occur to any appreciable extent, because operators at dust generating sites would be required to comply with the Best Available Control Measure (BACM) requirements of SCAQMD Rule 403 – Fugitive Dust. In general, operators must control fugitive dust through a number of soil stabilizing measures such as watering the site, using chemical soil stabilizers, revegetating inactive sites, etc. As the proposed project may involve the installation of add-on SOx control equipment, some grading or excavation could be required to provide stable foundation footings. Potential air quality impacts

related to grading are addressed elsewhere in this Air Quality section of this ~~Draft~~ Final PEA. No unstable earth conditions or changes in geologic substructures are expected to result from the proposed project.

Since the proposed project will affect existing facilities, it is expected that the soil types present at the affected facilities will not be further susceptible to expansion or liquefaction. Furthermore, subsidence is not anticipated to be a problem since few excavation, grading, or filling activities are expected occur at affected facilities. Additionally, the affected areas are not envisioned to be prone to landslides or have unique geologic features since the affected facilities are existing facilities that are typically located in industrial areas.

In addition, since the proposed project will affect existing facilities located in industrial, heavy manufacturing zones, it is expected that people or property will not be exposed to expansive soils or soils incapable of supporting water disposal. Further, typically each affected facility has some degree of existing wastewater treatment systems that will continue to be used. Sewer systems and in the case of the cement manufacturing facility, septic tank systems and percolation ponds, are available to handle wastewater produced and treated by each affected facility. Each existing facility affected by the proposed project does not require installation of new septic tanks or alternative wastewater disposal systems. As a result, the proposed project will not require operators to build new septic systems or alternative wastewater disposal systems. Thus, the proposed project will not adversely affect soils associated with constructing a new septic system or alternative wastewater disposal system.

Based upon the aforementioned considerations, significant geology and soils impacts are not expected from the implementation of the proposed project.

Land Use and Planning

The proposed project does not require construction of new facilities, but any physical effects will occur at existing facilities and, thus, it will not result in physically dividing any established communities. There are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Further, the proposed project would be consistent with the typical industrial, heavy manufacturing zoning of the affected facilities. All proposed modifications are expected to occur within the confines of the existing facilities. The proposed project would not affect in any way habitat conservation or natural community conservation plans, agricultural resources or operations, and would not create divisions in any existing communities. Further, no new development or alterations to existing land designations will occur as a result of the implementation of the proposed project. Therefore, present or planned land uses in the region will not be affected as a result of the proposed project. Based upon these considerations, significant land use planning impacts are not expected from the implementation of the proposed project.

Mineral Resources

There are no provisions of the proposed project that would result in the loss of availability of a known mineral resource of value to the region and the residents of the state such as aggregate, coal, clay, shale, et cetera, or of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Noise

Modifications or changes associated with the implementation of the proposed project will take place at existing facilities that are located in industrial, heavy manufacturing settings. The existing noise environment at each of the affected facilities is typically dominated by noise from existing equipment onsite, vehicular traffic around the facilities, and trucks entering and exiting each facility premises. Construction activities for the proposed project may generate some noise associated with the use of construction equipment and construction-related traffic in the event that grading for the installation of the SOx control equipment, for example, is necessary. However, noise from the proposed project, whether from construction or operation activities, is not expected to produce noise in excess of current operations measurable at the property line of each of the existing facilities. If SOx control equipment is installed, the operations phase of the proposed project may add new sources of noise to each affected facility. However, it is expected that each facility affected will comply with all existing noise control laws or ordinances. Further, Occupational Safety and Health Administration (OSHA) and California-OSHA (CalOSHA) have established noise standards to protect worker health. These potential noise increases are not expected to be noticeable at the property line and further, are expected within the allowable noise levels established by the local noise ordinances for industrial areas, and thus are expected to be less than significant.

Though some of the facilities affected by the proposed project are located at sites within an airport land use plan, or within two miles of a public airport, the addition of SOx control equipment would not expose people residing or working in the project area to an additional degree of excessive noise levels associated with airplanes. All noise producing equipment must comply with local noise ordinances and applicable OSHA or CalOSHA workplace noise reduction requirements. Based upon the aforementioned considerations, significant noise impacts are not expected from the implementation of the proposed project.

Population and Housing

The construction activities associated with the proposed project at each affected facility are not expected to involve the relocation of individuals, require new housing or commercial facilities, or change the distribution of the population. The reason for this conclusion is that operators of affected facilities who need to perform any construction activities to comply with the proposed project can draw from the existing labor pool in the local southern California area. For example, the analysis of air quality impacts for the proposed project assumed 50 construction workers would be necessary to install one WGS or DGS. The "worst-case" analysis further assumed that up to four units could be under construction during any six-month construction period. This translates to the need of 200 construction workers during any six-month construction period. Construction crews comprising of 200 individuals can easily be drawn from the local labor force.

Further, it is not expected that the installation of the SOx control equipment will require new employees during operation of the equipment. In the event that new employees are hired, it is expected that the number of new employees at any one facility would be small. Human population within the jurisdiction of the SCAQMD is anticipated to grow regardless of implementing the proposed project. As a result, the proposed project is not anticipated to generate any significant adverse effects, either direct or indirect, on population growth in the District or population distribution.

Because the proposed project includes modifications and/or changes at existing facilities located in industrial, heavy manufacturing settings, the proposed project is not expected to result in the

creation of any industry that would affect population growth, directly or indirectly induce the construction of single- or multiple-family units, or require the displacement of people or housing elsewhere in the District. Based upon these considerations, significant population and housing impacts are not expected from the implementation of the proposed project.

Public Services

Implementation of the proposed project is expected to cause facility operators to install SOx control devices, all the while continuing current operations at existing affected facilities. The proposed project may result in a greater demand for catalyst and scrubbing agents, which will need to be transported to the affected facilities that install SOx controls and stored onsite prior to use. In the event of an accidental release, fire departments are typically first responders for control and clean-up and police may be need to be available to maintain perimeter boundaries. The proposed project is not expected to have a significantly adverse affect on fire or police departments because of the low probability of accidents during transport as explained below.

The factors that enter into accident statistics include distance traveled and type of vehicle or transportation system. Factors affecting automobiles and truck transportation accidents include the type of roadway, presence of road hazards, vehicle type, maintenance and physical condition, driver training, and weather. A common reference frequently used in measuring risk of an accident is the number of accidents per million miles traveled. Complicating the assessment of risk is the fact that some accidents can cause significant damage without injury or fatality and some accidents result in little or no property damage or personal injury. Additionally, not every truck accident results in an explosion or a release of hazardous substances.

Every time hazardous materials are moved from the site of generation, there is the potential for accidental release. A study conducted by the USEPA indicates that the expected number of hazardous materials spills per mile shipped ranges from one in 100 million to one in one million, depending on the type of road and transport vehicle used. The USEPA analyzed accident and traffic volume data from New Jersey, California, and Texas, using the Resource Conservation and Recovery Act Risk/Cost Analysis Model and calculated the accident rates presented in Table 4-54. This information was summarized from the Los Angeles County Hazardous Waste Management Plan (Los Angeles County, 1988).

In the study completed by USEPA, cylinders, cans, glass, plastic, fiber boxes, tanks, metal drum/parts, and open metal containers were identified as usual container types. For each container type, the expected fractional release en route was calculated. The study concluded that the release rate for tank trucks is much lower than for any other container type (Los Angeles County, 1988).

Table 4-54
Truck Accident Rates For Cargo On Highways

Highway Type	Accidents Per 1,000,000 miles
Interstate	0.13
Federal and State Highways	0.45
Urban Roadways	0.73
Composite*	0.28

Source: USEPA, 1984.
* Average number for transport on interstates, highways, and urban roadways.

Based on the low probability of accidents occurring, as shown in Table 4-54, the proposed project is not expected to increase the need or demand for additional public services (e.g., fire departments, police departments, schools, parks, government, et cetera) above current levels.

As noted in the previous "Population and Housing" discussion, the proposed project is not expected to induce population growth in any way because the local labor pool (e.g., workforce) is expected to be sufficient to accommodate any construction activities that may be necessary at affected facilities and operation of new or modified equipment is not expected to require additional employees. Therefore, there will be no increase in local population and thus no impacts are expected to local schools or parks.

The proposed project is expected to result in the installation of SOx control equipment. Besides permitting the equipment or altering permit conditions by the SCAQMD, there is no need for other types of government services. The proposed project would not result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times, or other performance objectives. There will be no increase in population and, therefore, no need for physically altered government facilities. Based upon these considerations, significant public services impacts are not expected from the implementation of the proposed project.

Recreation

As discussed previously under "Land Use," there are no provisions to the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments; no land use or planning requirements are expected to be altered by the proposed project. Further, the proposed project would not increase the use of existing neighborhood and regional parks or other recreational facilities or include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment because the proposed project is not expected to induce population growth. Based upon these considerations, significant recreation impacts are not expected from the implementation of the proposed project.

Solid/Hazardous Waste

Construction activities associated with installing SOx control equipment such as WGSs, demolition and site preparation/grading/excavating could generate solid waste as result of implementing the proposed project. Demolition activities could generate demolition waste while site preparation, grading, and excavating could uncover contaminated soils since the facilities affected by the proposed project are located in existing industrial areas. Excavated soil, which may be contaminated, will need to be characterized, treated, and disposed of offsite in accordance with applicable regulations. Where appropriate, the soil will be recycled if it is considered or classified as non-hazardous waste or it can be disposed of at a landfill that accepts non-hazardous waste. Otherwise, the material will need to be disposed of at a hazardous waste facility. (Potential soil contamination is addressed in the Hazards/Hazardous Materials discussion in Section VIII. d.)

Solid or hazardous wastes generated from construction-related activities would consist primarily of materials from the demolition of existing air pollution control equipment and construction associated with new or modified air pollution control equipment. Construction-related waste would be disposed of at a Class II (industrial) or Class III (municipal) landfill. There are 48 Class II/Class III landfills within the SCAQMD's jurisdiction. Based on a search of the

California Integrated Waste Management Board's Solid Waste Information System (SWIS) on May 16, 2007, the landfills that accept construction waste in Los Angeles, Orange, Riverside and San Bernardino counties have a combined remaining disposal capacity of approximately 750,846,000 cubic yards (1,250,367,507 tons).

Solid waste is expected to be generated from operational activities associated with implementation of the proposed project. Of the potential SOx control technologies, the largest amount of solid waste is expected to be generated from the operation of WGSs. Table 4-55 summarizes the potential generation of solid waste per source category that may be generated by either Option 1 or Option 2 of the proposed project.

Tab1e 4-55
Summary of Potential Operational Increases in Solid Waste Generation by Source Category

Source Category	Option 1: Proposed Control Technology	Option 1: Potential Increase in Solid Waste to be Generated (tons/day)	Option 2: Proposed Control Technology	Option 2: Potential Increase in Solid Waste to be Generated (tons/day)
FCCU	WGS	4.19	SOx Reducing Additives	0
SRU/TGU	WGS	2.25	WGS	2.25
Refinery Boilers/Heaters	FGT	2.33	FGT	2.33
Coke Calciner	WGS	0.44	WGS	0.44

Based on the composition of the solid waste that may be generated, most of the solid waste would be considered a commodity and is expected to be transported to a cement plant for recycling while some will be reused on site, depending on the facility. Tables 4-56 and 4-57 summarize the amount of waste that may be generated and how it may be handled for both Options 1 and 2 of the proposed project.

The generation of catalyst fines and any other solid waste is expected to be captured by the control equipment as wet solids. In most cases, these wet solids can be collected for recycling for use in manufacturing cement. For the purpose of this analysis, this practice would be expected to continue if the proposed project is implemented because all but one of the refineries operating FCCUs currently send their spent catalyst to a local cement plant for reuse in the cement manufacturing process. In addition, for reducing SOx from SRU/TGUs during operation, the use of selective oxidation catalyst may be used at Facility A. However, the precious metal content (platinum) and relatively high cost of the catalyst, recycling, instead of disposal, is expected to occur with this product.

For these reasons, the projected solid waste data obtained by the consultant from each affected facility indicated that the waste may be treated as a commodity and is not expected to be disposed of in a landfill. Instead the solid waste will either be sent to a cement plant for

recycling or re-used on site. In any case, even if the entire amount of solid waste generated was sent to a landfill, it would not exceed the capacity of the designated landfills. Refer to Appendix B for the solid waste data. Therefore, less than significant adverse impacts to non-hazardous waste disposal facilities are expected from operational activities associated with the proposed project.

Table 4-56
Option 1: Summary of Potential Operational Increases in Solid Waste Generation by Facility

Facility ID	Option 1: Proposed Control Technology	Potential Increase in Solid Waste to be Generated from Proposed Project (tons/day)	How will Solid Waste be handled?

K	2 DGSs for cement kilns (new)	2.49	Will remain on-site for reuse
	TOTAL	**7.56**	

However, it is expected that some affected facilities may address the increase in waste through existing waste minimization plans. In addition, other affected facilities that have existing catalyst-based operations currently regenerate, reclaim or recycle the catalysts, in lieu of disposal. Moreover, due to the heavy metal content and its relatively high cost, catalyst recycling can be a lucrative choice.

Although it is expected that spent catalysts would be reclaimed and recycled, it is possible that spent catalysts could be disposed of. The composition of the catalyst will determine in which type of landfill a catalyst would be disposed. There are two main types of catalysts: one in

which the catalyst is coated onto a metal structure and a ceramic-based catalyst onto which the catalyst components are calcified.

A catalyst with a metal structure would not normally be considered a hazardous waste. Instead, it would be considered a metal waste, like copper pipes, and, therefore, would not be a regulated waste requiring disposal in a Class I landfill unless it is friable or brittle. Ceramic-based catalysts are not considered friable or brittle because they typically include a fiber binding material in the catalyst material. In both cases, spent catalyst would not require disposal in a Class I landfill. Furthermore, typical catalyst materials are not considered to be water soluble, which also means they would not require disposal in a Class I landfill.

Based on the aforementioned information, it is likely that spent catalysts would be considered a "designated waste," which is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state (CCR, Title 23, Chapter 3, Subparagraph 2522(a)(1)). Depending on their actual waste designation, spent catalysts would likely be disposed of in a Class II landfill or a Class III landfill that is fitted with liners. According to the Final Program EIR for the 2007 AQMP (SCAQMD, 2007), total Class III landfill waste disposal capacity in the District is approximately 93,979 tons per day, many of which have liners and can handle Class II and Class III wastes.

Disposal of spent catalyst would typically involve crushing the material and encasing it in concrete prior to disposal. Since it is expected that most spent catalysts will be recycled and regenerated, it is anticipated that there will be sufficient landfill capacity in the District to accommodate disposal of any spent catalyst materials. Thus, the potential increase of solid waste generated by the air pollution control equipment may not necessarily be disposed of and, therefore, is not expected to exceed the capacity of designated landfills available to each affected facility. Further, implementing the proposed project is not expected to hinder in any way any affected facility's ability to comply with existing federal, state, and local regulations related to solid and hazardous wastes. Based upon these considerations, significant solid/hazardous waste impacts are not expected from the implementation of the proposed project.

SIGNIFICANT IRREVERSIBLE ENVIRONMENTAL CHANGES

CEQA Guidelines §15126(c) requires an environmental analysis to consider "any significant irreversible environmental changes which would be involved if the proposed action should be implemented." This PEA identified the topic of air quality as the environmental area potentially adversely affected by the proposed project. The NOP/IS also identified aesthetics, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic as significant, but after further analysis, these topics were determined to have less than significant impacts. Significant adverse impacts from GHGs generated from both construction and operation activities may be considered irreversible. Facility operators that install new SOx controls or modify existing units are likely to operate these systems for the lifetime of the equipment.

POTENTIAL GROWTH-INDUCING IMPACTS

CEQA Guidelines §15126(d) requires an environmental analysis to consider the "growth-inducing impact of the proposed action." Implementing the proposed project will not, by itself,

have any direct or indirect growth-inducing impacts on businesses in the SCAQMD's jurisdiction because it is not expected to foster economic or population growth or the construction of additional housing and primarily affects existing facilities.

CONSISTENCY

CEQA Guidelines §15125(d) requires an EIR to discuss any inconsistencies between a proposed project and any applicable general plans or regional plans. SCAG and the SCAQMD have developed, with input from representatives of local government, the industry community, public health agencies, the USEPA - Region IX and CARB, guidance on how to assess consistency within the existing general development planning process in the Basin. Pursuant to the development and adoption of its Regional Comprehensive Plan Guide (RCPG), SCAG has developed an Intergovernmental Review Procedures Handbook (June 1, 1995). The SCAQMD also adopted criteria for assessing consistency with regional plans and the AQMP in its CEQA Air Quality Handbook. The following sections address the consistency between the proposed project and relevant regional plans pursuant to the SCAG Handbook and SCAQMD Handbook.

Consistency with Regional Comprehensive Plan and Guide (RCPG) Policies

The RCPG provides the primary reference for SCAG's project review activity. The RCPG serves as a regional framework for decision making for the growth and change that is anticipated during the next 20 years and beyond. The Growth Management Chapter (GMC) of the RCPG contains population, housing, and jobs forecasts, which are adopted by SCAG's Regional Council and that reflect local plans and policies, shall be used by SCAG in all phases of implementation and review. It states that the overall goals for the region are to: 1) re-invigorate the region's economy; 2) avoid social and economic inequities and the geographical isolation of communities; and, 3) maintain the region's quality of life.

Consistency with Growth Management Chapter (GMC) to Improve the Regional Standard of Living

The Growth Management goals are to develop urban forms that enable individuals to spend less income on housing cost, that minimize public and private development costs, and that enable firms to be more competitive, strengthen the regional strategic goal to stimulate the regional economy. The proposed project in relation to the GMC would not interfere with the achievement of such goals, nor would it interfere with any powers exercised by local land use agencies. Further, the proposed project will not interfere with efforts to minimize red tape and expedite the permitting process to maintain economic vitality and competitiveness.

Consistency with Growth Management Chapter (GMC) to Provide Social, Political and Cultural Equity

The Growth Management goals to develop urban forms that avoid economic and social polarization promotes the regional strategic goals of minimizing social and geographic disparities and of reaching equity among all segments of society. Consistent with the Growth Management goals, local jurisdictions, employers and service agencies should provide adequate training and retraining of workers, and prepare the labor force to meet the challenges of the regional economy. Growth Management goals also includes encouraging employment development in job-poor localities through support of labor force retraining programs and other economic development measures. Local jurisdictions and other service providers are responsible to develop sustainable communities and provide, equally to all members of society, accessible and effective services such as: public education, housing, health care, social services,

recreational facilities, law enforcement, and fire protection. Implementing the proposed project has no effect on and, therefore, is not expected to interfere with the goals of providing social, political and cultural equity.

Consistency with Growth Management Chapter (GMC) to Improve the Regional Quality of Life

The Growth Management goals also include attaining mobility and clean air goals and developing urban forms that enhance quality of life, accommodate a diversity of life styles, preserve open space and natural resources, are aesthetically pleasing, preserve the character of communities, and enhance the regional strategic goal of maintaining the regional quality of life. The RCPG encourages planned development in locations least likely to cause environmental impacts, as well as supports the protection of vital resources such as wetlands, groundwater recharge areas, woodlands, production lands, and land containing unique and endangered plants and animals. While encouraging the implementation of measures aimed at the preservation and protection of recorded and unrecorded cultural resources and archaeological sites, the plan discourages development in areas with steep slopes, high fire, flood and seismic hazards, unless complying with special design requirements. Finally, the plan encourages mitigation measures that reduce noise in certain locations, measures aimed at preservation of biological and ecological resources, measures that would reduce exposure to seismic hazards, minimize earthquake damage, and develop emergency response and recovery plans. The proposed project implements an AQMP control measure, which results in improving air quality in the region. Therefore, in relation to the GMC, the proposed project is not expected to interfere, but rather help with attaining and maintaining the air quality portion of these goals.

Consistency with Regional Mobility Element (RMP) and Congestion Management Plan (CMP)

The proposed project is consistent with the RMP and CMP since less than significant adverse impacts to transportation/circulation will result from installing SOx control equipment at affected facilities. There will be an increase of one-way truck transport trips to deliver fresh catalyst and dispose of, or recycle spent catalyst, and to deliver NaOH and other substances as a result of the proposed project. The peak daily truck transport trips associated with these activities would be 33 under Option 1 and 30 under Option 2 of the proposed project. Because these trips would not likely all occur on the same day and because they would be dispersed over a wide area, the proposed project is not expected to significantly adversely affect circulation patterns or congestion management.

C H A P T E R 5

A L T E R N A T I V E S

INTRODUCTION

This ~~Draft~~ Final PEA provides a discussion of alternatives to the proposed project as required by CEQA. Alternatives include measures for attaining objectives of the proposed project and provide a means for evaluating the comparative merits of each alternative. A 'no project' alternative must also be evaluated. The range of alternatives must be sufficient to permit a reasoned choice, but need not include every conceivable project alternative. CEQA Guidelines §15126.6(c) specifically notes that the range of alternatives required in a CEQA document is governed by a 'rule of reason' and only necessitates that the CEQA document set forth those alternatives necessary to permit a reasoned choice. The key issue is whether the selection and discussion of alternatives fosters informed decision making and meaningful public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative. SCAQMD Rule 110 (the rule which implements the SCAQMD's certified regulatory program) does not impose any greater requirements for a discussion of project alternatives in an environmental assessment than is required for an EIR under CEQA.

Three alternatives to the proposed project are summarized in Table 5-1: Alternative A (No Project), Alternative B (AQMP), and Alternative C (Intermediate SOx Reductions). Pursuant to the requirements in CEQA Guidelines §15126.6 (b) to mitigate or avoid the significant effects that a project may have on the environment, a comparison of the potential air quality impacts from each of the project alternatives for the individual rule components that comprise the proposed project is provided in Table 5-2. The alternatives comparison in Table 5-2 also addresses the topics of aesthetics, energy, hazards and hazardous materials, hydrology and water quality, and transportation/traffic. Aside from these topics, no other significant adverse impacts were identified for the proposed project or any of the project alternatives. The proposed project is considered to provide the best balance between emission reductions and the adverse environmental impacts due to construction and operation activities while meeting the objectives of the project. Therefore, the proposed project is preferred over the project alternatives.

Table 5-1
Summary of PAR 2002 & Project Alternatives

Rule Components									
Basic Equipment	**BARCT**	**Proposed Project**	**SOx Reduction Potential** (tons/day)	**Alternative A:** No Project	**SOx Reduction Potential** (tons/day)	**Alternative B:** AQMP	**SOx Reduction Potential** (tons/day)	**Alternative C:** Intermediate SOx Reductions	**SOx Reduction Potential** (tons/day)
FCCU	WGS or SOx Reducing Additive	5 ppm SOx (3.25 lbs SOx/1000 bbl)	2.88[88]	No SOx limit	0	Same as Alternative A: No Project	0	Same as Proposed Project	2.88[88]
SRU/TGU	WGS or Selective Oxidation Catalyst	5 ppm SOx (combusted tail gas) & 10 ppm H2S / 300 ppm non-H2S (non-combusted tail gas) (5.28 lbs SOx/hr)	0.73[89]	No SOx limit	0	Same as Alternative A: No Project	0	Same as Alternative A: No Project	0

2005 Excess SOx RTCs			1.75		0		1.75		1.75
Minimum SOx Emission Reductions Needed[88]			**4.39**		**0**		**1.25**		**3.57**

Key: WGS = Wet Gas Scrubber; DGS = Dry Gas Scrubber; FGT = Fuel Gas Treatment

[88] The estimated amount of SOx potentially reduced excludes the data for Facility D because installing a WGS is not cost-effective for this facility. However, the estimated amount of SOx potentially reduced includes the data for Facility C because a WGS is already installed.

[89] The estimated amount of SOx potentially reduced excludes the data for Facility E and Facility G because installing a WGS or Emerachem unit is not cost-effective for these facilities.

[90] This equipment is currently not operating at Facility K.

[91] The proposed project neither establishes a new BARCT level for refinery boilers/heaters nor requires additional reductions from this source category. However, cost-effective emission reductions in the amount of 0.85 tons per day are potentially available from future retrofits in this source category and the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave.

Less than significant, but less than the proposed project for both Options 1 and 2.

ALTERNATIVES REJECTED AS INFEASIBLE

A CEQA document should identify any alternatives that were considered by the lead agency, but were rejected as infeasible during the scoping process and explain the reasons underlying the lead agency's determination [CEQA Guidelines §15126.6(c)]. No alternative was specifically rejected as being infeasible.

LOWEST TOXIC ALTERNATIVE

In accordance with SCAQMD's policy document Environmental Justice Program Enhancements for FY 2002-03, Enhancement II-1 recommends that all SCAQMD CEQA assessments include a feasible project alternative with the lowest air toxics emissions. In other words, for any major equipment or process type under the scope of the proposed project that creates a significant environmental impact, at least one alternative, where feasible, shall be considered from a "least harmful" perspective with regard to hazardous air emissions. With respect to the proposed project, a lowest air toxics alternative would be to use SOx control technology that uses the least amount of toxic materials. The main SOx reduction technology considered for the proposed project is based on employing WGSs, but other types of SOx controls, such as SOx reducing additives and DGSs, may also be employed. The analysis shows that of the proposed SOx controls, only WGSs may increase the use of toxic materials. Specifically, some WGSs, but not all, rely on the use of sodium hydroxide (NaOH) caustic solution as the scrubbing agent. NaOH is a toxic air contaminant (TAC) that is a non-cancerous but acutely hazardous substance and is used in WGSs for controlling SOx emissions from FCCUs, coke calciners, sulfuric acid manufacturing and glass melting.

As a point of contrast, WGSs employed for controlling SOx from SRU/TGUs use sodium carbonate (Na2CO3) which is commonly known as soda ash, a non-toxic, non-cancerous, and non-hazardous substance, as the scrubbing agent. Further, DGSs employed for controlling SOx from cement kilns utilize limestone, also a non-toxic, non-cancerous, and non-hazardous substance, as the scrubbing agent. If SOx reducing additives (catalyst) are employed in lieu of WGSs for FCCUs, the catalyst is also non-toxic, non-cancerous, and non-hazardous substance.

Lastly, FGT for refinery boilers and heaters will vary from process-to-process and facility-to-facility, but none would require WGS technology. FGT, does involve the use of various substances, depending on the process, such as NaOH caustic, amines, and specialty catalysts. As demonstrated in the hazards discussion in Chapter 4 of this PEA, only the NaOH caustic employed for FGT is hazardous. Table 5-3 contains a summary of the substances used per process per source category and indicates if the substance is toxic.

Table 5-3
Potential Increase in Substances Used in SOx Control Technologies

Equipment/Source Category	Control Technology	Substances	Is the substance a toxic air contaminant (TAC)?
FCCU	WGS	NaOH	**Yes**
FCCU	SOx Reducing Additive	Proprietary catalyst blend	No
SRU/TGU	WGS	Soda Ash	No
SRU/TGU	Selective Oxidation Catalyst	Proprietary catalyst blend	No
Sulfuric Acid Mfg.	WGS	NaOH	**Yes**
Coke Calciner	WGS	NaOH	**Yes**
Glass Melting Furnace	WGS	NaOH	**Yes**
Cement Kiln	DGS	Limestone	No
Coal-fired Boiler	DGS	Limestone	No
Refinery Boilers/ Heaters	FGT	NaOH, proprietary catalyst blend or amines	**Yes, for NaOH**

Based on Table 5-3, the use of NaOH defines which portions of the project and various alternatives are toxic. In addition, each facility that was projected to increase the use in the acutely hazardous substance NaOH under Alternatives B and C, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities for any of the alternatives. Because the screening level for NaOH was not exceeded for any of the affected facilities, no significant air quality operational impacts with respect to toxics are expected from any of the alternatives. NaOH is not classified as a carcinogen, so a cancer risk analysis for each of the alternatives was not performed.

To determine the lowest toxic alternative, Table 5-4 contains a comparison of the proposed project and each alternative relative to the amount of NaOH that may be used per source category.

Table 5-4
Summary of Potential NaOH Use per Source Category

Projected Increased Amount of NaOH To Be Used (tons/day)							
Equipment/ Source Category	**Control Technology that Uses NaOH**	**Proposed Project: Option 1**	**Proposed Project: Option 2**	**Alternative A: No Project**	**Alternative B: AQMP**	**Alternative C: Intermediate SOx Reductions – Option 1**	**Alternative C: Intermediate SOx Reductions – Option 2**
FCCU	WGS	4.45	0*	0	0*	4.45	0*
Sulfuric Acid	WGS	1.30	1.30	0	1.30	1.30	1.30
Coke Calciner	WGS	3.37	3.37	0	3.37	3.37	3.37
Glass Melting Furnace	WGS	0.79	0.79	0	0.79	0.79	0.79
Refinery Boilers & Heaters	FGT	3.34	3.34		0	3.34	3.34
	TOTAL	**13.24**	**8.79**	**0**	**5.45**	**13.24**	**8.79**

*The Proposed Project- Option 2, Alternative B and Alternative C – Option 2 are based on the assumption that SOx reducing additives will be used in lieu of WGS technology for FCCUs.

As shown in Table 5-4, Alternative A has least amount of toxics involved because no NaOH would be used. However, because Alternative A is the 'no project alternative,' it does not achieve the goals of the proposed project because it does not implement the AQMP control measure. Therefore, Alternative A cannot be considered the lowest toxic alternative. Of the alternatives that achieve the goals of the AQMP control measure, Alternative B uses the least amount of NaOH (5.45 tons per day) when compared to the Proposed Project (e.g., 13.24 tons per day under Option 1 and 8.79 tons per day under Option 2). Therefore, when compared to the Proposed Project and the other alternatives under consideration that also rely on the use of NaOH for compliance, Alternative B can be considered the lowest toxic alternative.

DESCRIPTION OF ALTERNATIVES

The following proposed alternatives were developed by modifying specific components of the proposed project. The rationale for selecting and modifying specific components of the proposed project to generate feasible alternatives for the analysis is based on CEQA's requirement to present "realistic" alternatives; that is, alternatives that can actually be implemented.

The initial analysis of the proposed project in the NOP/IS determined that, of the amendments proposed, only the components that pertain to the lowered SOx emission limits could entail physical modifications to the affected equipment that could have potential adverse significant impacts. As such, the following three alternatives were developed by identifying and modifying major components of the proposed project. Specifically, the primary components of the proposed alternatives that have been modified are the source categories that may be affected, and the manner in which compliance with the proposed SOx emission limits may be achieved. The alternatives, summarized in Table 5-1 and described in the following subsections, include the following: Alternative A (No Project), Alternative B (AQMP), and Alternative C (Intermediate SOx Reductions). Unless otherwise specifically noted, all other components of the project

alternatives are identical to the components of the proposed project. The following subsections provide a brief description of each alternative.

Alternative A - No Project

Alternative A or 'no project' means that the proposed project would not be adopted and the current universe of equipment will continue to be maintained at their current operations without being required to further reduce SOx emissions. However, by not adopting the SOx emission limits for each source category as proposed, the current version of Rule 2002 would not implement AQMP Control Measure CMB-02: Further SOx Reduction for RECLAIM (CM #2007CMB-02). In summary, Alternative A, the 'no project' alternative, does not achieve the goals of the proposed project because it does not implement the AQMP control measure. While no significant adverse secondary environmental impacts would result from the 'no project' alternative, it is not necessarily the environmentally superior alternative in accordance with CEQA Guidelines §15126.6(e)(2) because SOx emissions would continue to be emitted at current levels, thus, not improving air quality in the District.

Alternative B – AQMP

Alternative B is the AQMP alternative with the top three most cost-effective SOx emission reduction targets that focus on the following equipment/source categories: 1) sulfuric acid manufacturing; 2) coke calciner; and, 3) glass melting furnaces. Under Alternative B, less add-on control equipment (e.g., four WGSs) would be expected to be installed in order to achieve SOx emission reductions as compared to the proposed project (e.g., 11 WGSs plus two DGSs under Option 1 and seven WGSs plus two DGSs under Option 2). The reduced number of add-on controls to be installed under Alternative B when compared to the proposed project can be attributed to the exclusion of the following source categories: FCCU, SRU/TGU, cement kiln, and refinery boilers/heaters. Having equivalent SOx emission limits implemented on only the most cost-effective source categories means that the overall SOx emission reductions attributable to Alternative B will be much less than the proposed project for both Options 1 and 2. Significant adverse air quality impacts for criteria pollutants during construction would result from implementing Alternative B. Because of the potential for four WGSs to be constructed simultaneously under Alternative B, the peak daily construction emissions would be equivalent to the proposed project for both Options 1 and 2. However, because less add-on control equipment would be installed overall under Alternative B when compared to the proposed project, the operation GHG emissions would be less than significant and substantially less than the proposed project for both Options 1 and 2. In addition, less than significant adverse secondary impacts for aesthetics, energy, hazards and hazardous materials, hydrology and water quality, and transportation and traffic are expected to result from implementing Alternative B, but these impacts would also be less than the proposed project.

Alternative C – Intermediate SOx Reductions

Alternative C would impose the same SOx limits on fewer equipment/source categories when compared to both Options 1 and 2 of the proposed project. Specifically, five equipment/source categories comprise Alternative C: FCCUs, sulfuric acid manufacturing, coke calciner, glass melting furnaces, and cement kilns. Like the proposed project, there are two SOx control approaches that can be applied to FCCUs under Alternative C. For this reason, Alternative C has been bifurcated into two options: Option 1 assumes that WGSs will be the control approach for FCCUs; and, Option 2 assumes that SOx reducing additives will be the control approach for FCCUs. The remaining source categories and their respective control approaches applicable to Alternative C will be the same for both Option 1 and Option 2.

Under Alternative C, less add-on control equipment (e.g., eight WGSs plus two DGSs under Option 1 and four WGSs plus two DGSs under Option 2) would be expected to be installed under Alternative C in order to achieve the lowered SOx emission limits as compared to the Proposed Project compared to the proposed project (e.g., 11 WGSs plus two DGSs under Option 1 and seven WGSs plus two DGSs under Option 2). The reduced number of add-on control equipment to be installed under Option 2 can be attributed to the assumption that SOx reduction catalysts could be utilized in the FCCUs. Having equivalent SOx emission limits applied to fewer source categories means that the overall SOx emission reductions attributable to Alternative C will be less than the proposed project (e.g., 5.48 tons per day versus 6.21 tons per day). Significant adverse air quality impacts for criteria pollutants during construction and GHGs during operation would result from implementing Alternative C for both Options 1 and 2. Like the proposed project, the simultaneous construction of four WGSs is assumed to occur under both Options 1 and 2 for Alternative C. Thus, the peak daily construction emissions for both Options 1 and 2 of Alternative C would be equivalent to the both Options 1 and 2 of the proposed project. However, because less WGSs would be installed overall under Alternative C when compared to the proposed project, the operation GHG emissions would be less than both Options 1 and 2 of the proposed project. In addition, less than significant adverse secondary impacts for aesthetics, energy, hazards and hazardous materials, hydrology and water quality, and transportation and traffic are expected to result from implementing Alternative C, but these impacts would also be less than both Options 1 and 2 of the proposed project.

COMPARISON OF THE ALTERNATIVES

The Environmental Checklist (see Chapter 2 of the Initial Study in Appendix C) identified only aesthetics, air quality, energy, hazards and hazardous materials, hydrology and water quality, and transportation and traffic as the environmental areas that could be significantly adversely affected by the proposed project. Further evaluation of potential impacts in Chapter 4 of this Environmental Assessment determined that the proposed project for both Options 1 and 2 would not generate significant adverse project-specific impacts for aesthetics, energy, hazards and hazardous materials, , and transportation and traffic. Instead, only the project-specific air quality impacts and hydrology (water demand) impacts were concluded to be significant.

The following sections describe the potential adverse impacts that may be generated by each project alternative. Potential adverse impacts for the environmental topics are quantified where sufficient data are available. A comparison of the environmental impacts for each project alternative is provided in Table 5-2. No other environmental topics other than air quality were determined to be significantly adversely affected by implementing any project alternative.

AESTHETICS

Alternative A - No Project

The project-specific aesthetic impacts associated with the installation of multiple WGSs would be eliminated under Alternative A, the no project alternative, since no construction activities would occur and no new equipment would be installed at any of the affected facilities. Under Alternative A, the aesthetic impacts would remain unchanged from the existing setting and therefore, would be less than significant.

Alternative B – AQMP

Alternative B contains the same SOx emission reduction targets as the proposed project but only for the following equipment/source categories: sulfuric acid manufacturing, coke calciner, and glass melting furnace. As with the proposed project, Alternative B would result in the installation of multiple WGSs that would generate multiple visible steam plumes and would require new, tall stacks for each WGS creating adverse aesthetics impacts. However, because less source categories are included in Alternative B, less WGSs would be installed when compared to the proposed project (e.g., four WGSs versus 11 WGSs for Option 1 and seven WGSs for Option 2). The reduced number of WGSs to be installed under Alternative B when compared to the proposed project can be primarily attributed to the exclusion of the FCCU and SRU/TGU source categories and focusing on the top three most cost-effective SOx reduction targets. The aesthetics impacts associated with the proposed project for both Options 1 and 2 were considered to be less than significant because the new WGSs to be installed would occur within existing heavy industrial areas. While less WGSs would be installed under Alternative B, aesthetics impacts are expected to occur but they will be less than the proposed project. Thus, Alternative B is considered to have less than significant aesthetics impacts.

Alternative C – Intermediate SOx Reductions

Alternative C would impose the same SOx limits on fewer equipment/source categories when compared to the proposed project. Specifically, five equipment/source categories comprise Alternative C: FCCUs, sulfuric acid manufacturing, coke calciner, glass melting furnaces, and cement kilns. As with the proposed project, Alternative C would result in the installation of multiple WGSs that would generate visible steam plumes and would require new, tall stacks for each WGS creating adverse aesthetics impacts. However, less WGSs (e.g., four) would be installed under Alternative C (e.g., eight WGSs under Option 1 and four WGSs under Option 2) when compared to the proposed project (e.g., 11 WGSs under Option 1 and seven WGSs under Option 2). The reduced number of WGSs to be installed under Alternative C – Option 2 can be attributed to the assumption that SOx reduction catalysts could be utilized in the FCCUs thus eliminating the need for add-on control equipment for this source category. The aesthetics impacts associated with both Options 1 and 2 of the proposed project were considered to be less than significant because the new WGSs to be installed would occur within existing heavy industrial areas. While less WGSs would be installed under both Options 1 and 2 of Alternative C, aesthetics impacts are expected to occur but they will be less than the proposed project. Thus, Alternative C is considered to have less than significant aesthetics impacts.

AIR QUALITY

Alternative A - No Project

Unlike the proposed project, it is not anticipated that Alternative A would generate significant adverse impacts during construction or operational activities because the owners/operators of affected equipment/source categories would not be expected to modify their operations in a way that could generate construction and operation emissions. Instead, owners/operators of the affected equipment/source categories would continue existing operations in compliance with the current SOx RECLAIM program as well as complying with all applicable SCAQMD, CARB and USEPA requirements. By not adopting the proposed project, current operations mean that each facility can continue to operate their SOx emitting equipment in accordance with their annual SOx allocations and SOx RTCs. This means that there would be SOx reductions and health benefits from reducing overall SOx emissions will not be realized. Further, by not implementing

SOx emission reductions, AQMP Control Measure CMB-02: Further SOx Reduction for RECLAIM (CM #2007CMB-02, would not be implemented. In summary, Alternative A, the 'no project' alternative, does not achieve the goals of the proposed project because it does not implement the AQMP control measure or comply with state law to implement all feasible mitigation measures.

Alternative B – AQMP

Because Alternative B applies the same SOx emission reduction targets as the proposed project but to fewer equipment/source categories (e.g., sulfuric acid manufacturing, coke calciner, and glass melting furnace), less emission reductions (i.e., 1.5 tons per day for Alternative B versus 6.2 tons per day for the proposed project) would be realized for less affected equipment (i.e., the installation of four WGSs for Alternative B versus 11 WGSs plus two DGSs for Option 1 of the proposed project or seven WGSs plus two DGSs for Option 2 of the proposed project). Due to the limited focus of Alternative B, fewer WGSs will be installed. Further, because there will be fewer WGSs installed that also utilize NaOH, less operational emissions associated with NaOH deliveries and use will occur with Alternative B when compared to the proposed project. Similar to the proposed project, it is anticipated that the installation of WGSs in accordance with Alternative B would generate significant adverse construction and operational air quality impacts, but these impacts would be less than the proposed project because less add-on control equipment would be installed.

In summary, if Alternative B were implemented, less SOx reductions would be achieved and less health benefits from reducing SOx overall will be realized. Alternative B does not achieve as great of SOx emission reduction benefits as the proposed project. Table 5-1 summarizes the SOx emission reduction benefits per day for Alternative B (i.e., approximately 1.5 tons per day).

Table 5-5 presents the results of the SCAQMD staff's construction air quality analysis for the proposed project and lists the peak daily construction emissions from construction worker trips and use of equipment for the installation of one WGS and the overlapping construction of four WGSs, respectively. For construction, Alternative B is equivalent to the proposed project, because both assume the peak daily construction of four WGSs. For the installation of one WGS, the calculations show the total daily construction emissions exceed the SCAQMD's CEQA air quality significance threshold of 100 pounds of NOx per day. For the simultaneous construction of four WGSs, the calculations show the total daily construction emissions exceed the SCAQMD's CEQA air quality significance thresholds of 100 pounds of NOx per day, 75 pounds of VOC per day, and 150 pounds of PM10 per day. Appendix B contains the spreadsheets with the results and assumptions used by the SCAQMD staff for this analysis.

Table 5-5
Alternative B: Peak Daily "Worst-Case" Construction Emissions from the Installation of WGS Technology in 2012 or later

Peak Construction Activity	VOC (lbs/day)	CO (lbs/day)	NOx (lbs/day)	SOx (lbs/day)	PM10 (lbs/day)	PM2.5 (lbs/day)
Phase I: Demolition	6	32	40	0	2	2
Phase II: Construction	16	83	76	0	38	11
Total for 1 WGS Installation	**22**	**115**	**116**	**0**	**40**	**13**
SIGNIFICANCE THRESHOLD	75	550	100	150	150	55
SIGNIFICANT?	**NO**	**NO**	**YES**	**NO**	**NO**	**NO**
Phase I: Demolition	24	129	161	0	9	8
Phase II: Construction	65	332	303	1	150	45
Total for 4 WGS Installations	**89**	**461**	**464**	**1**	**159**	**53**
SIGNIFICANCE THRESHOLD	75	550	100	150	150	55
SIGNIFICANT?	**YES**	**NO**	**YES**	**NO**	**YES**	**NO**

With regard to greenhouse gas emissions, Tables 5-6 and 5-7 summarize the CO2 impacts from both construction activities and operation activities associated with the installation of four WGS for Alternative B on a source category and facility-by-facility basis, respectively. The CO2 impacts from construction were amortized over a 30-year period. The peak operational emissions are based on the operations of the SOx control equipment plus the anticipated increase in truck hauling and deliveries as a result of maintaining the SOx control equipment. Though the peak operational emissions are assumed to occur no sooner than 2012, all operational emissions are expected to occur by the end of year 2018 because the compliance date of the proposed project is January 1, 2019.

Table 5-6
Alternative B: Overall CO2eq Increases Due to Construction and Operation Activities per Source Category (metric tons/year)[1]

K	0	0	0	0	0	0	0
TOTAL	**312**	**0**	**6,020**	**169**	**55**	**11**	**6,567**

[1] 1 metric ton = 2,205 pounds
[2] GHGs from temporary construction activities are amortized over 30 years.

Even though Alternative B is expected to generate construction-related CO2 emissions, and the operational phase of the proposed project is also expected to generate additional GHG emissions, none of the affected facilities individually exceed the GHG industrial significance threshold of 10,000 MT/day. Further, the collective GHG emissions from the three source categories under

Alternative B do not exceed the threshold. Therefore, Alternative B is expected to have less than significant GHG impacts.

Emission sources associated with the operational-related activities as a result of implementing Alternative B may emit TACs because caustic is used in the operation of certain WGS. With the potential for the installation of four WGS under Alternative B, that means a maximum of four caustic storage tanks may be installed. There are several types of caustic solutions that can be used in WGS operations, but sodium hydroxide (NaOH) is the most commonly used. NaOH is a toxic air contaminant that is a non-cancerous but acutely hazardous substance. For "worst-case" operations, 5.45 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate four WGSs under Alternative B. Even though the facilities that may be affected by Alternative B may currently use NaOH elsewhere in their facilities, for the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for every WGS installed. Of the four facilities that would be affected by Alternative B, three were projected to have an increased demand in NaOH use for WGS operations. As summarized in Table 5-8, for each facility that was projected to increase the use of the acutely hazardous substance NaOH, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities. Because the screening level for NaOH was not exceeded for any of the affected facilities, no significant air quality operational impacts with respect to toxics are expected from the proposed project. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed.

Alternative C – Intermediate SOx Reductions

Alternative C proposes the same SOx emission reduction targets as the proposed project for the following equipment/source categories: FCCUs, sulfuric acid manufacturing, coke calciner,

glass melting furnace, and cement kilns. Like the proposed project, there are two SOx control approaches that can be applied to FCCUs under Alternative C. For this reason, Alternative C has been bifurcated into two options: Option 1 assumes that WGSs will be the control approach for FCCUs; and, Option 2 assumes that SOx reducing additives will be the control approach for FCCUs. The remaining source categories and their respective control approaches applicable to Alternative C will be the same for both Option 1 and Option 2.

Because less add-on control equipment would be expected to be installed under Alternative C (i.e., eight WGSs plus two DGSs under Option 1 and four WGSs plus two DGSs under Option 2) in order to achieve the proposed SOx emission limits as compared to the proposed project (i.e., 11 WGSs plus two DGSs for Option 1 and seven WGSs plus to DGSs under Option 2), Alternative C would result in less emission reductions (i.e., 5.48 tons per day for Alternative C versus 6.21 tons per day for the proposed project). The reduced number of add-on control equipment to be installed under Option 2 can be attributed to the assumption that SOx reduction catalysts could be utilized in the FCCUs in lieu of WGSs.

Further, there will be the same number of WGSs that utilize NaOH installed, so equivalent operational emissions associated with NaOH deliveries will occur under Alternative C when compared to the proposed project for both options. Similar to the proposed project, it is anticipated that the installation of add-on control equipment in accordance with Alternative C would generate significant adverse construction and operational air quality impacts, but these impacts would be less than the both Options 1 and 2 of the proposed project because less control equipment would be installed.

In summary, if Alternative C were implemented, less SOx reductions would be achieved and less health benefits from reducing SOx overall will be realized. Alternative C achieves less SOx emission reduction benefits as both Options 1 and 2 of the proposed project. Table 5-1 summarizes the SOx emission reduction benefits per day for Alternative C (e.g., approximately 5.48 tons per day).

Table 5-9 presents the results of the SCAQMD staff's construction air quality analysis for the proposed project and lists the peak daily construction emissions from construction worker trips and use of equipment for the installation of one WGS and the overlapping construction of four WGSs, respectively. For construction, Alternative C is equivalent to the proposed project, because both assume the peak daily construction of four WGSs, even though the total number of add-on controls to be installed under Alternative C is 10 ~~eight~~ for Option 1 (eight ~~six~~ WGSs plus two DGSs) and six for Option 2 (four WGSs plus two DGSs). For the installation of one WGS, the calculations show the total daily construction emissions exceed the SCAQMD's CEQA air quality significance threshold of 100 pounds of NOx per day. For the simultaneous construction of four WGSs, the calculations show the total daily construction emissions exceed the SCAQMD's CEQA air quality significance thresholds of 100 pounds of NOx per day, 75 pounds of VOC per day, and 150 pounds of PM10 per day. Appendix B contains the spreadsheets with the results and assumptions used by the SCAQMD staff for this analysis.

With regard to greenhouse gas emissions, Tables 5-10 and 5-11 summarize the CO2eq impacts from both construction activities and operation activities associated with the installation of eight WGSs plus two DGSs under Option 1 of Alternative C on a source category and facility-by-facility basis, respectively. Similarly, Tables 5-12 and 5-13 summarize the CO2eq impacts from both construction activities and operation activities associated with the installation of four WGSs plus two DGSs under Option 2 of Alternative C on a source category and facility-by-facility basis, respectively. For both Options 1 and 2, the CO2eq impacts from construction were amortized over a 30-year period. The peak operational emissions are based on the operations of the SOx control equipment plus the anticipated increase in truck hauling and deliveries as a result of maintaining the SOx control equipment. Though the peak operational emissions are assumed to occur no sooner than 2012, all operational emissions are expected to occur by the end of year 2018 because the compliance date of the proposed project is January 1, 2019.

TOTAL	**621**	**-668**	**14,385**	**210**	**77**	**180**	**14,805**

[1] 1 metric ton = 2,205 pounds
[2] GHGs from temporary construction activities are amortized over 30 years.
[3] A negative number means a reduction in usage or demand.

While none of the affected facilities individually exceed the GHG industrial significance threshold of 10,000 MT/day under Option 1 or Option 2, the collective GHG emissions under

Alternative C exceed the threshold for both options. Therefore, Alternative C is expected to have adverse significant GHG impacts. Because Alternative C is expected to generate construction-related CO2 emissions, and the operational phase of the proposed project is also expected to generate additional GHG emissions, cumulative GHG adverse impacts from Alternative C are considered significant.

Emission sources associated with the operational-related activities as a result of implementing the Alternative C may emit TACs because caustic is used in the operation of a WGS. With the potential for the installation of eight WGSs under Option 1 and four WGSs under Option 2 for Alternative C, that means a maximum of eight caustic storage tanks under Option 1 and four caustic storage tanks under Option 2 may be installed to supply the WGSs. There are several types of caustic solutions that can be used in WGS operations, but sodium hydroxide (NaOH) is the most commonly used. NaOH is a toxic air contaminant that is a non-cancerous but acutely hazardous substance. In addition, two more NaOH storage tanks would be needed under both Option 1 and Option 2 to support the operations of two FGT modifications for the refinery boiler/heater source category at two facilities.

Of the facilities affected by the Alternative C, seven facilities were projected to have an increased demand in NaOH use for WGS operations plus two for FGT for refinery boilers and heaters under Option 1 and three facilities were projected to have an increased demand in NaOH use for WGS operations plus two for FGT for refinery boilers and heaters under Option 2.

For "worst-case" operations under Alternative C, 13.24 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate eight WGSs plus two FGTs for refinery boilers and heaters under Option 1 and 8.79 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate four WGSs plus two FGTs for refinery boilers and heaters under Option 2. For the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for every WGS installed and for every FGT modification that utilizes NaOH. As summarized in Tables 5-14 and 5-15, for each facility that was projected to increase the use in the acutely hazardous substance NaOH, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities under Option 1 or Option 2 for Alternative C. Because the screening level for NaOH was not exceeded for any of the affected facilities, no significant air quality operational impacts with respect to toxics are expected from Alternative C. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed for Alternative C.

Total	**8.79**					

ENERGY

Alternative A - No Project

The project-specific energy impacts associated with the installation of multiple SOx control devices (e.g., WGSs and DGSs) would be eliminated under Alternative A, the no project alternative, since no construction activities would occur and no new equipment would be installed at any of the affected facilities that would need additional electricity, natural gas, gasoline or diesel. Under Alternative A, the energy impacts would remain unchanged from the existing setting and therefore, would be less than significant.

Alternative B – AQMP

Because Alternative B applies the same SOx emission reduction targets as the proposed project but to less equipment/source categories (i.e., sulfuric acid manufacturing, coke calciner, and glass melting furnace), less add-on control equipment will be installed (i.e., four WGSs) such that less additional electricity, natural gas, gasoline or diesel would be needed for construction and operation activities. The following analysis will demonstrate that the projected increases in energy demand associated with Alternative B will be less than significant because the amount of additional electricity, natural gas, gasoline, and diesel needed to install and operate the new SOx controls was well below the applicable energy significance criteria. While fewer WGSs would be installed under Alternative B, adverse energy impacts are expected to occur but they will be less than the proposed project.

Energy information as it relates to construction and operational activities under Alternative B was derived as part of the air quality analysis in Chapter 4 and the calculations are shown in Appendix B of this ~~Draft~~ Final PEA. If the potential SOx controls are installed and operated on a per facility and per source category basis, respectively, Tables 5-16 and 5-17 summarize the estimated impacts on operational natural gas and electricity use for Alternative B on a facility and source category basis, respectively.

Table 5-16

	TOTAL	**0**	**33,064**

* A negative number means a reduction in usage or demand.

Table 5-17
Alternative B: Operational Energy Use By Source Category

Equipment/ Source Category	Natural Gas (MMBTU/day)	Electricity (kWh/day)
FCCUs	0	0
SRU/TGUs	0	0
Refinery Boilers/Heaters	0	0
Coke Calciner	0	17,711
Glass Melting Furnaces	0	5,694
Sulfuric Acid Manufacturing	0	9,659
Cement Kilns	0	0
TOTAL	**0**	**33,064**

The overall electricity needed to implement Alternative B includes the amount of electricity that may be needed to produce additional NaOH needed to operate certain WGSs. To determine if the operational energy use is significant for Alternative B, the total for natural gas and electricity was compared to the threshold fuel supply as shown in Table 5-18. California utilities and non-utilities have the ability to receive approximately 9,330 MMcf/day of natural gas[92], [93], [94]. Since Alternative B does not exceed the SCAQMD's energy threshold of one percent of supply for both natural gas and electricity, Alternative B is expected to have less than significant energy impacts. Further, because the increase in electricity demand for Alternative B is below the SCAQMD's energy significance threshold of one percent above available supplies as shown in Table 5-18 below, any increased demand that may result from Alternative B can likely be met with the existing electrical capacity at each of the affected facilities. Lastly, based on this analysis, it is not anticipated that new or substantially altered power utility systems will need to be built to accommodate any additional electricity demands created by Alternative B.

See Form 1.4 b, Peak Demand by LSE: summer Peak Demand Coincident with Planning Area Peak for the following agencies/areas: SCE (Anaheim, Azusa, Banning, Colton, Metropolitan Water District, Rancho Cucamonga, Riverside and Vernon), Cities of Burbank, Glendale and Pasadena, and LADWP. http://www.energy.ca.gov/2007publications/CEC-200-2007-015/CEC-200-2007-015-SF2.PDF

[c] SCAQMD's Energy Threshold for both Natural Gas and Electricity is 1% of Supply.

KEY: MMcf = million standard cubic feet
MW(Megawatt) = 1 MW = 1,000 kilowatts (KW)

In addition, Table 5-19 presents a summary of the total projected fuel usage (i.e., diesel and gasoline) for both construction and operational activities for Alternative B. The analysis shows an overall increase in diesel and gasoline use of approximately 1,465 gallons per day and 1,354 gallons per day, respectively. Since Alternative B does not exceed the SCAQMD's energy threshold of one percent of supply for both diesel and gasoline fuels as shown in Table 5-19 below, Alternative B is expected to have less than significant energy impacts due to fuel use. Further, once construction is completed, the fuel use projected during the temporary phases (e.g., Phase I: Demolition and Phase II: Construction) will end and only the fuel use for truck trips associated with chemical deliveries and solid waste removal activities during Phase III: Operations will continue. Thus, any potential adverse fuel impacts will likely be less than what has been analyzed during the peak for the proposed project.

Table 5-19
Alternative B: Total Projected Fuel Usage

Activity	Total Fuel Usage per Activity (gallons/day)	
	Diesel	Gasoline
Phase I - Demolition Overlapping with Phase II - Construction at Four Facilities (Construction Equipment and Workers Vehicles)	1,360	1,354
Phase III: Operation (Chemical Deliveries & Solid Waste Removal)	105	0
Total Usage for Alternative B	1,465	1,354
Threshold Fuel Supply[a]	1,086,000,000	6,469,000,000
% of Fuel Supply	0.0001%	0.00002%
Significant (Yes/No)[b]	No	No

[a] Year 2000 California Energy Commission (CEC) projections. Construction activities in future years would yield similar results.
[b] SCAQMD's energy threshold for both diesel and gasoline is 1% or more of supply.

Like the proposed project, Alternative B is not subject to any existing energy conservation plans. If any facility that is subject to Alternative B is also subject to energy conservation plans, it is not expected that Alternative B will affect in any way or interfere with that individual facility's ability to comply with its energy conservation plan or energy standards. Further, construction and operation activities under Alternative B will not utilize non-renewable resources in a wasteful or inefficient manner. Lastly, it is expected that the installation and operation of any equipment used to comply with Alternative B will also comply with all applicable existing energy standards. In summary, the energy impacts from Alternative B are concluded to be less than significant.

Alternative C – Intermediate SOx Reductions

Alternative C proposes the same SOx emission reduction targets as the proposed project for the following equipment/source categories: FCCUs, sulfuric acid manufacturing, coke calciner, glass melting furnace, and cement kilns. Like the proposed project, there are two SOx control approaches that can be applied to FCCUs under Alternative C. For this reason, Alternative C has been bifurcated into two options: Option 1 assumes that WGSs will be the control approach for FCCUs; and, Option 2 assumes that SOx reducing additives will be the control approach for FCCUs. The remaining source categories and their respective control approaches applicable to Alternative C will be the same for both Option 1 and Option 2.

Because less add-on control equipment would be expected to be installed under Alternative C (i.e., eight WGSs plus two DGSs under Option 1 and four WGSs plus two DGSs under Option 2) in order to achieve the proposed SOx emission limits as compared to the proposed project (i.e., 11 WGSs plus two DGSs for Option 1 and seven WGSs plus to DGSs under Option 2), the following analysis shows that both Options 1 and 2 under Alternative C would result in less demand for energy when compared to the proposed project. While less SOx add-on controls

would be installed under Alternative C for both Options 1 and 2, adverse energy impacts are expected to occur but they will be less than the proposed project.

Energy information as it relates to construction and operational activities was derived as part of the air quality analysis in Chapter 4 and the calculations are shown in Appendix B of this ~~Draft~~ Final PEA. If the potential SOx controls are installed and operated on a per facility and per source category basis for Option 1 under Alternative C, respectively, Tables 5-20 and 5-21 summarize the estimated impacts on operational natural gas and electricity use for Option 1. Similarly, Tables 5-22 and 5-23 summarize the estimated impacts on operational natural gas and electricity use for Alternative C - Option 2.

Sulfuric Acid Manufacturing	0	9,659
Cement Kilns	0	23,288
TOTAL	**-34.25***	**79,000**

* A negative number means a reduction in usage or demand.

For Alternative C - Option 1, the analysis shows an overall decrease in natural gas demand of approximately 34.25 MMBTU per day (equivalent to 0.034 MMcf/day) and an overall increase in electricity demand of 182,218 kWh/day (equivalent to 182 MWh/day) for the affected source categories. For Alternative C - Option 2, the analysis shows the same overall decrease in natural gas demand as Alternative C – Option 1, approximately 34.25 MMBTU/day (equivalent to 0.034 MMcf/day) and an overall increase in electricity demand of 79,000 kWh/day (equivalent to 79 MWh/day) for the affected source categories.

In addition, as part of operation for some WGSs and FGTs, NaOH caustic soda solution is required. For Alternative C - Option 1, 13.24 tons per day of NaOH is estimated to be needed and for Alternative C - Option 2, 8.79 tons per day of NaOH may be needed. NaOH is produced locally by several chemical processing companies and as such, is locally available for transport. Further, it is likely that the existing local caustic manufacturers can handle the proposed increase in caustic for the entire project. To accommodate the estimated increase in caustic demand, the chemical processing companies may need to increase production, which, in turn, will use more electricity. It takes approximately 2,500 kWh to produce one metric ton of NaOH. Thus, the approximate amount of additional electricity that may be needed to produce additional caustic to meet the needs of Option 1 and Option 2 under Alternative C, are 30,023 kWh/day and 19,940 kWh/day, respectively, and are calculated as follows:

Alternative C - Option 1:

$$\frac{13.24 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{Ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = \textbf{30,023 kWh/day}$$

Alternative C - Option 2:

$$\frac{8.79 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{Ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = \textbf{19,932 kWh/day}$$

The overall electricity needed to implement both Options 1 and 2 under Alternative C as summarized in Tables 5-20, 5-21, 5-22 and 5-23 include the amount of electricity that may be needed to produce additional NaOH. To determine if the operational energy use is significant for Options 1 and 2 under Alternative C, the total for natural gas and electricity was compared to the threshold fuel supply as shown in Table 5-24. California utilities and non-utilities have the

ability to receive approximately 9,330 MMcf/day of natural gas[95], [96], [97]. Since both Options 1 and 2 under Alternative C do not exceed the SCAQMD's energy threshold of one percent of supply for both natural gas and electricity, Alternative C is expected to have less than significant energy impacts. Further, because the increase in electricity demand for both Options 1 and 2 under Alternative C is below the SCAQMD's energy significance threshold of one percent above available supplies, any increased demand that may result from either Option 1 or 2 under Alternative C can likely be met with the existing electrical capacity at each of the affected facilities. Lastly, based on this analysis, it is not anticipated that new or substantially altered power utility systems will need to be built to accommodate any additional electricity demands created by either Option 1 or 2 under Alternative C.

Table 5-24
Alternative C: Total Projected Natural Gas and Electricity Impacts for Operation Activities

Operation Activity	Total Energy Usage per Activity	
	Natural Gas[a]	Electricity
Alternative C -Option 1	-0.034 MMcf	182 MWh/day = 7.6 MW (instantaneous)
Threshold Fuel Supply	9,330 MMcf[b]	8,362 MW[c] (instantaneous)
% of Fuel Supply	-0.0004 %	0.09%
Significant (Yes/No)[d]	No	No
Alternative C - Option 2	-0.034 MMcf	79 MWh/day = 3.3 MW (instantaneous)
Threshold Fuel Supply	9,330 MMcf[b]	8,362 MW[c] (instantaneous)
% of Fuel Supply	-0.0004 %	0.04%
Significant (Yes/No)[d]	No	No

[a] A negative number is a reduction in the use of natural gas consumption.

[d] SCAQMD's Energy Threshold for both Natural Gas and Electricity is 1% of Supply.

KEY: MMcf = million standard cubic feet
MW(Megawatt) = 1 MW = 1,000 kilowatts (KW)

In addition, Table 5-25 presents a summary of the total projected fuel usage (i.e., diesel and gasoline) for both construction and operational activities for both Options 1 and 2 under

[95] Natural Gas Infrastructure – Draft Staff Paper, California Energy Commission, CEC-200-2009-004-SD, May 2009. http://www.energy.ca.gov/2009publications/CEC-200-2009-004/CEC-200-2009-004-SD.PDF
[96] 2008 California Gas Report, Prepared by the California Gas and Electric Utilities. http://www.energy.ca.gov/2008publications/GAS-1000-2008-020/GAS-1000-2008-020.PDF
[97] An Overview of Natural Gas in California, California Energy Commission, CEC-180-2008-005, April 2008. http://www.energy.ca.gov/2008publications/CEC-180-2008-005/CEC-180-2008-005.PDF

Alternative C. For Alternative C - Option 1, the analysis shows an overall increase in diesel and gasoline use of approximately 3,493 ~~2,410~~ gallons per day and 1,354 ~~1,384~~ gallons per day, respectively. Similarly for Alternative C - Option 2, the analysis shows an overall increase in diesel and gasoline use of approximately ~~2,180~~ 3,127 gallons per day and 1,354 ~~1,384~~ gallons per day, respectively.

Since neither Option 1 nor Option 2 under Alternative C exceeds the SCAQMD's energy threshold of one percent of supply for both diesel and gasoline fuels as shown in Table 5-25 below, both Options 1 and 2 under Alternative C are expected to have less than significant energy impacts due to fuel use. Further, once construction is completed, the fuel use projected during the temporary phases (e.g., Phase I: Demolition and Phase II: Construction) will end and only the fuel use for truck trips associated with chemical deliveries and solid waste removal activities during Phase III: Operations will continue. Thus, any potential adverse fuel impacts will likely be less than what has been analyzed during the peak under Alternative C.

Table 5-25
Alternative C: Total Projected Fuel Usage

Activity	Total Fuel Usage per Activity (gallons/day)	
	Diesel	**Gasoline**
Alternative C - Option 1: Phase I - Demolition Overlapping with Phase II - Construction at Four Facilities (Construction Equipment and Workers Vehicles)	1,360	1,354
Alternative C - Option 1: Phase III: Operation (Chemical Deliveries & Solid Waste Removal)	2,133~~1,703~~	0
Total Usage for Alternative C - Option 1:	3,493~~3,063~~	1,354
Threshold Fuel Supply[a]	1,086,000,000	6,469,000,000
% of Fuel Supply	0.0003%	0.00002%
Significant (Yes/No)[b]	No	No
Alternative C - Option 2: Phase I - Demolition Overlapping with Phase II - Construction at Four Facilities (Construction Equipment and Workers Vehicles)	1,360	1,354
Alternative C - Option 2: Phase III: Operation (Chemical Deliveries & Solid Waste Removal)	1,767~~1330~~	0
Total Usage for Alternative C - Option 2:	3,127~~2,690~~	1,354
Threshold Fuel Supply[a]	1,086,000,000	6,469,000,000
% of Fuel Supply	0.0003~~2~~%	0.00002%
Significant (Yes/No)[b]	No	No

[a] Year 2000 California Energy Commission (CEC) projections. Construction activities in future years would yield similar results.
[b] SCAQMD's energy threshold for both diesel and gasoline is 1% or more of supply.

Like the proposed project, neither Option 1 nor Option 2 under Alternative C is subject to any existing energy conservation plans. If any facility that is subject to Alternative C is also subject to energy conservation plans, it is not expected that Alternative C will affect in any way or interfere with that individual facility's ability to comply with its energy conservation plan or energy standards. Further, construction and operation activities under Alternative C will not utilize non-renewable resources in a wasteful or inefficient manner. Lastly, it is expected that the installation and operation of any equipment used to comply with Alternative C will also comply with all applicable existing energy standards. In summary, the energy impacts from both Option 1 and Option 2 under Alternative C are concluded to be less than significant.

HAZARDS AND HAZARDOUS MATERIALS

Alternative A - No Project

Alternative A is not expected to generate significant adverse hazards and hazardous materials impacts primarily because the owners/operators of the affected sources would not have to install new or modify existing control equipment (i.e., WGSs, DGSs, SOx-reducing additives, et cetera) whereby no additional SOx emissions would be reduced and no new hazards regarding the handling of hazardous materials would be needed, such as deliveries of NaOH. Further, Alternative A is not expected to alter the deliveries, use and amounts of NaOH at the affected facilities. Instead, owners/operators of affected facilities would continue existing operations that would comply with all applicable existing SCAQMD, CARB and USEPA requirements. By not adopting the proposed project, with respect to hazards and hazardous materials, current operations at each facility would be expected to continue to emit SOx at the levels allowed by the current version of Regulation XX without impacting the deliveries, quantities, and use (or disposal) of hazardous materials (NaOH).

Alternative B – AQMP

Because Alternative B applies the same SOx emission reduction targets as the proposed project but to less equipment/source categories (i.e., sulfuric acid manufacturing, coke calciner, and glass melting furnace), less add-on control equipment will be installed (i.e., four WGSs). Table 5-26 summarizes the substances that are currently used and that may be used in response to Alternative B.

Table 5-26
Alternative B: Substances To Be Used by SOx Control Technologies

Equipment/ Source Category	Current SOx Control Technology	Substances Currently Used for SOx Control	Proposed SOx Control Technology	Proposed Substances To Be Used/Increased for SOx Control
Sulfuric Acid	Catalytic Converter	Catalyst	1 WGS for 1 facility (new)	NaOH Caustic
Sulfuric Acid	Cansolv Unit	Cansolv amine	1 Upgrade to Existing Cansolv Unit for 1 facility (modified)	Water
Coke Calciner	DGS	CaOH absorbent	1 WGS for 1 facility (new)	NaOH Caustic
Glass Melting Furnace	DGSs	Trona	2 WGSs for 1 facility (new)	NaOH Caustic

Key: WGS = Wet Gas Scrubber; DGS = Dry Gas Scrubber

Table 5-27 summarizes the substances that may be involved in the various processes at the affected facilities under Alternative B. Some of the substances listed are considered hazardous while others are not. Of the substances listed, the only net increase in the use of a hazardous material will be for NaOH. For the remaining substances identified, there will be either a decrease in use or no change from the existing setting under Alternative B.

Table 5-27
Alternative B: Substances that May Be Affected By The Proposed Project

Substance	Potential Overall Increase, Decrease, or No Change from Existing Setting?	Contains TAC(s) per SCAQMD Rule 1401?	Hazardous per CalARP?	NFPA Rating: Health (Blue)	NFPA Rating: Flammability (Red)	NFPA Rating: Reactivity (Yellow)	NFPA Rating: Special (White)
NaOH Caustic (50% by weight)	Increase	Yes, Acute (non-cancer)	Yes	3	0	1	None
Sulfuric Acid	No Change	Yes, cancer/ chronic & acute	Yes	3	0	2	Water Reactive
Cansolv	No Change	Yes, cancer/ chronic & acute	Yes	N/A	N/A	N/A	N/A
COS	Decrease	No	Yes	2	0	1	None
H2S	Decrease	Yes, cancer/ chronic & acute	Yes	4	4	0	None
SO2	Decrease	No	Yes	3	0	0	None
SO3	Decrease	Yes, cancer/ chronic & acute (pending)	Yes	3	0	2	None

NFPA Hazard Code Key: 4 = Extreme; 3 = High; 2 = Moderate; 1 = Slight; 0 = Insignificant; N/A = NFPA hazard is not assigned.

Emission sources associated with the operational-related activities as a result of implementing Alternative B may emit TACs because NaOH caustic is used to operate WGSs for the affected source categories. With the potential for the installation of four WGS under Alternative B, that means a maximum of four NaOH storage tanks may be installed. As previously analyzed in the air quality discussion, NaOH is a toxic air contaminant that is a non-cancerous but acutely hazardous substance. For "worst-case" operations, 5.45 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate four WGSs under Alternative B. Even though the facilities that may be affected by Alternative B may currently use NaOH elsewhere in their facilities, for the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for every WGS installed. Of the four facilities that would be affected by Alternative B, three were projected to have an increased demand in NaOH use for WGS operations. As summarized in Table 5-28, for each facility that was projected to increase the use in the acutely hazardous substance NaOH, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities. Because the screening level for NaOH was not exceeded for any of the affected facilities, no significant air quality operational impacts with respect to toxics are expected from the proposed project. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed.

Table 5-28
Alternative B: Summary of Filling and Working Losses for NaOH Storage Tanks

Facility ID	Projected Increase in NaOH Demand (tons/day)	A: Hourly NaOH (as PM10) Filling Loss (lb/hr)	B: Hourly NaOH (as PM10) Working Loss (lb/hr)	A + B = Total Hourly NaOH (as PM10) Losses (lb/hr)	NaOH Acute Screening Level at 25 meters (lb/hr)	Do Total Hourly Losses Exceed Acute Screening Level For NaOH? Total	**5.45**					

To accommodate the increased demand in NaOH, there will be an increase in truck deliveries to supply NaOH to the facilities that need it. It is expected that the affected facilities will receive NaOH from a local supplier located in the greater Los Angeles area. Deliveries of NaOH (50 percent by weight) would be made by tanker truck via public roads. The maximum capacity of a NaOH tanker truck is approximately 6,000 gallons. The projected onsite storage capacity and consumption rates of NaOH as well as the projected annual deliveries are summarized in Table 5-29. Based on the annual deliveries estimates, each facility is not expected to exceed the peak daily of one delivery per day per facility. However, the "worst-case" assumption for a peak daily

delivery frequency from a supplier would be to deliver 6,000 gallons of NaOH to each of four facilities to fill four new NaOH tanks on the same day. Regulations for the transport of hazardous materials by public highway are described in 49 CFR §§ 173 and 177.

Table 5-29
Alternative B: Summary of NaOH Deliveries

Total	**5.45**	**1,990**	**53**

[1] Annual NaOH deliveries are calculated based on one delivery truck holding 6,000 gallons per truck load. For example, for Facility H: 1,228 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 192,326 gal/year x 1 truck/6,000 gallons = 32 trucks/year.

The onsite storage and handling of NaOH creates the possibility of an accidental spill and release of NaOH. However, because NaOH has such a low vapor pressure (6.33 mm Hg at 40 ^{o}C or 104 ^{o}F) when compared to water (55.3 mm Hg at 40 ^{o}C 104 ^{o}F) at the same temperature, any spill of NaOH would not be expected to evaporate faster than water. Thus any spill of NaOH would be expected to stay in liquid form and would not likely exceed the ERPG-2 vapor concentration of five milligrams per cubic meter for NaOH. Further, operators at each affected facility who construct a new NaOH storage tank will need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release due to tank rupture. Thus, any spill of NaOH would not be expected to migrate beyond the boundaries of the berm on-site. Thus, any spill of NaOH is not expected to present a potential offsite public and sensitive receptor exposure. Lastly, since NaOH is not a flammable compound, other types of heat-related hazard impacts such as fires, explosions, boiling liquid – expanding vapor explosion (BLEVE) are not expected to occur and, therefore, will not be evaluated as part of this hazards analysis.

In conclusion, the hazards and hazardous materials impacts due to the use, tank rupture and the accidental release of NaOH will be less than significant for Alternative B.

Alternative C – Intermediate SOx Reductions

Alternative C proposes the same SOx emission reduction targets as the proposed project for the following equipment/source categories: FCCUs, sulfuric acid manufacturing, coke calciner, glass melting furnace, and cement kilns. Like the proposed project, there are two SOx control approaches that can be applied to FCCUs under Alternative C. For this reason, Alternative C has been bifurcated into two options: Option 1 assumes that WGSs will be the control approach for FCCUs; and, Option 2 assumes that SOx reducing additives will be the control approach for

FCCUs. The remaining source categories and their respective control approaches applicable to Alternative C will be the same for both Option 1 and Option 2.

Because less add-on control equipment would be expected to be installed under Alternative C (i.e., eight WGSs plus two DGSs under Option 1 and four WGSs plus two DGSs under Option 2) in order to achieve the proposed SOx emission limits as compared to the proposed project (i.e., 11 WGSs plus two DGSs for Option 1 and seven WGSs plus to DGSs under Option 2), less hazardous materials would needed under Alternative C. Table 5-30 summarizes the substances that are currently used and that may be used in response to Alternative C.

Table 5-30
Alternative C: Substances To Be Used by SOx Control Technologies

Equipment/ Source Category	Current SOx Control Technology	Substances Currently Used for SOx Control	Proposed SOx Control Technology	Proposed Substances To Be Used/Increased for SOx Control
FCCU	SOx Reducing Additives	Specialty Catalyst	Option 1: WGSs Option 2: Increase amount of SOx Reducing Additives	Option 1: NaOH Caustic Option 2: Specialty Catalyst
Sulfuric Acid	Catalytic Converter	Catalyst	1 WGS for 1 facility (new)	NaOH Caustic
Sulfuric Acid	Cansolv Unit	Cansolv amine	1 Upgrade to Existing Cansolv Unit for 1 facility (modified)	Water
Coke Calciner	DGS	CaOH absorbent	1 WGS for 1 facility (new)	NaOH Caustic
Glass Melting Furnace	DGSs	Trona	2 WGSs for 1 facility (new)	NaOH Caustic
Cement Kiln	None	None	2 DGS (Limestone Absorber) for 1 facility (new)	Limestone
Refinery Boilers/ Heaters	Amine Absorbers	Amines (MEA & DEA)	3 FGTs by Sulfinol Conversion for 3 facilities (modified)	Sulfolane and DIPA
Refinery Boilers/ Heaters	Amine Absorbers	Amine (MEA) & Caustic (NaOH)	2 FGTs by Merox Treatment Upgrades for 2 facilities (modified)	1. Merox Catalyst 2. NaOH Caustic
Refinery Boilers/ Heaters	Amine Absorbers	Amine (MDEA)	1 FGT by Amine Additive for 1 facility (modified)	TG-10 amine

Key: WGS = Wet Gas Scrubber; DGS = Dry Gas Scrubber; FGT = Fuel Gas Treatment

Table 5-31 summarizes the substances that may be involved in the various processes at the affected facilities under Alternative C. Some of the substances listed are considered hazardous while others are not. Of the substances listed in Table 5-31, the only net increase in the use of a hazardous material will be for NaOH. For the remaining substances identified, there will be either a decrease in use or no change from the existing setting under Alternative C.

Table 5-31
Alternative C: Substances that May Be Affected By The Proposed Project

Substance	Potential Overall Increase, Decrease, or No Change from Existing Setting?	Contains TAC(s) per SCAQMD Rule 1401?	Hazardous per CalARP?	NFPA Rating: Health (Blue)	NFPA Rating: Flammability (Red)	NFPA Rating: Reactivity (Yellow)	NFPA Rating: Special (White)

NFPA Hazard Code Key: 4 = Extreme; 3 = High; 2 = Moderate; 1 = Slight; 0 = Insignificant; N/A = NFPA hazard is not assigned.

Emission sources associated with the operational-related activities as a result of implementing the Alternative C may emit TACs because NaOH caustic is used in the operation of the WGSs. With the potential for the installation of eight WGSs under Option 1 and four WGSs under Option 2 for Alternative C, that means a maximum of eight NaOH caustic storage tanks under Option 1 and four NaOH caustic storage tanks under Option 2 may be installed to supply the WGSs. NaOH is a toxic air contaminant that is a non-cancerous but acutely hazardous substance. In addition, two more NaOH storage tanks would be needed under both Option 1 and

Option 2 to support the operations of two FGT modifications for the refinery boiler/heater source category at two facilities.

Of the facilities affected by the Alternative C, seven facilities were projected to have an increased demand in NaOH use for WGS operations plus two for FGT for refinery boilers and heaters under Option 1 and three facilities were projected to have an increased demand in NaOH use for WGS operations plus two for FGT for refinery boilers and heaters under Option 2.

For "worst-case" operations under Alternative C, 13.24 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate eight WGSs plus two FGTs for refinery boilers and heaters under Option 1 and 8.79 tons per day of NaOH (50 percent solution, by weight) is estimated to be needed to operate four WGSs plus two FGTs for refinery boilers and heaters under Option 2. For the purpose of conducting a "worst-case" construction analysis, one 10,000 gallon storage tank for caustic solution was assumed to be constructed for every WGS installed and for every FGT modification that utilizes NaOH. As summarized in Tables 5-32 and 5-33, for each facility that was projected to increase the use in the acutely hazardous substance NaOH, the filling loss and the working loss of each NaOH tank was calculated, added together, and that sum was compared to the most stringent Rule 1401 Screening Emission Level for NaOH (0.004 pounds per hour at the nearest receptor distance of 25 meters). None of the total hourly loss projections exceeded the acute screening level for NaOH for any of the affected facilities under Option 1 or Option 2 for Alternative C. Because the screening level for NaOH was not exceeded for any of the affected facilities, no significant air quality operational impacts with respect to toxics are expected from Alternative C. NaOH is not classified as a carcinogen, so a cancer risk analysis was not performed for Alternative C.

To accommodate the increased demand in NaOH, there will be an increase in truck deliveries to supply NaOH to the facilities that need it. It is expected that the affected facilities will receive NaOH from a local supplier located in the greater Los Angeles area. Deliveries of NaOH (50 percent by weight) would be made by tanker truck via public roads. The maximum capacity of a NaOH tanker truck is approximately 6,000 gallons. The projected onsite storage capacity and consumption rates of NaOH as well as the projected annual deliveries are summarized in Tables 5-34 and 5-35 for Options 1 and 2 of Alternative C, respectively. Based on the annual deliveries estimates, each facility is not expected to exceed the peak daily of one delivery per day per facility. However, the "worst-case" assumption for a peak daily delivery frequency from a supplier would be to deliver 6,000 gallons of NaOH to each of four facilities to fill four new NaOH tanks on the same day. Regulations for the transport of hazardous materials by public highway are described in 49 CFR §§ 173 and 177.

Table 5-34
Alternative C - Option 1: Summary of NaOH Deliveries

Facility ID	Daily Increase in NaOH Demand (tons/day)	Annual Increase in NaOH Demand (tons/year)	Annual NaOH Deliveries [1] (truck trips/year)

I	0.79	289	8
J	1.30	473	13
K	0	0	0
Total	**8.79**	**3,210**	**86**

[1] Annual NaOH deliveries are calculated based on one delivery truck holding 6,000 gallons per truck load. For example, for Facility A: 294 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 46,045 gal/year x 1 truck/6,000 gallons = 8 trucks/year.

The onsite storage and handling of NaOH creates the possibility of an accidental spill and release of NaOH. However, because NaOH has such a low vapor pressure (6.33 mm Hg at 40 ^{o}C or 104 ^{o}F) when compared to water (55.3 mm Hg at 40 ^{o}C 104 ^{o}F) at the same temperature, any spill of NaOH would not be expected to evaporate faster than water. Thus any spill of NaOH would be expected to stay in liquid form and would not likely exceed the ERPG-2 vapor concentration of five milligrams per cubic meter for NaOH. Further, operators at each affected facility who construct a new NaOH storage tank will need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release due to tank rupture. Thus, any spill of NaOH would not be expected to migrate beyond the boundaries of the berm on-site.

Thus, any spill of NaOH is not expected to present a potential offsite public and sensitive receptor exposure. Lastly, since NaOH is not a flammable compound, other types of heat-related hazard impacts such as fires, explosions, boiling liquid – expanding vapor explosion (BLEVE) are not expected to occur and, therefore, will not be evaluated as part of this hazards analysis.

In conclusion, the hazards and hazardous materials impacts due to the use, tank rupture and the accidental release of NaOH will be less than significant for Alternative C.

HYDROLOGY AND WATER QUALITY

Alternative A - No Project

The project-specific hydrology and water quality impacts associated with the installation of multiple SOx control devices (e.g., WGSs and DGSs) would be eliminated under Alternative A, the no project alternative, since no construction activities would occur and no new equipment would be installed at any of the affected facilities that would need additional water or would generate additional wastewater. Under Alternative A, the hydrology and water quality impacts would remain unchanged from the existing setting and therefore, would be less than significant.

Alternative B – AQMP

Because Alternative B applies the same SOx emission reduction targets as the proposed project but to less equipment/source categories (e.g., sulfuric acid manufacturing, coke calciner, and glass melting furnace), less add-on control equipment will be installed (i.e., four WGSs) such that less water demand and wastewater generation would occur. The following analysis will demonstrate that the projected increases in water demand and wastewater generation associated with Alternative B will be less than significant because the amount of additional water demand and wastewater generation associated with the installation and operation of the new SOx controls are below the applicable hydrology and water quality significance criteria. While less WGSs would be installed under Alternative B, adverse hydrology and water quality impacts are expected to occur but they will be less than the proposed project.

Water demand and wastewater generation information as it relates to construction and operational activities under Alternative B was derived as part of the hydrology and water quality analysis in Chapter 4 and the calculations are shown in Appendix B of this ~~Draft~~ Final PEA.

Construction Water Demand

Implementation of Alternative B is expected to result in construction activities associated with installing new or modifying existing SOx control equipment at the affected facilities, which are complex, well-established and mostly paved, industrial facilities. Depending on the proposed location within each facility's boundaries for the siting of any new control equipment that may be installed as a result of implementing Alternative B, construction activities such as digging, earthmoving, grading, slab pouring, or paving could occur if the proposed site for the new equipment is not suitable in its present form (e.g., graded with a foundation slab). Table 5-36 contains a summary of the estimates of plot space needed per facility under Alternative B.

Table 5-36
Alternative B: Potential Plot Space Needed For Proposed Control Technologies

Facility ID	Potential SOx Control	Plot Space Needed for Proposed Controls (square feet)
A	Not applicable to Alternative B	**0**
B	Not applicable to Alternative B	**0**
C	1 Upgrade to Existing Cansolv Unit/Sulfuric Acid (modified)	**0**
D	Not applicable to Alternative B	**0**
E	Not applicable to Alternative B	**0**
F	Not applicable to Alternative B	**0**
G	Not applicable to Alternative B	**0**
H	1 WGS for calciner (new)	**1,200**
I	2 WGSs for glass melting furnaces (new)	**640**
J	1 WGS for sulfuric acid unit (new)	**500**
K	Not applicable to Alternative B	**0**
	TOTAL	**2,340**

Based on the consultant's surveys of the affected facilities, if all affected facilities conduct site preparation activities, the total amount of disturbed area for all of the facilities combined is estimated to be 2,340 square feet (0.05 acre) under Alternative B. However, even if all affected facilities intend to conduct site preparation, not much overlap of site preparation activities would be expected since there are several years between the proposed rule amendment date (2010) and the proposed compliance date (January 1, 2019) and because the plot spaces are small. Further, depending on the scale, site preparation typically can take anywhere from two weeks to one month. Therefore, it is unlikely that all affected facilities will do site preparation both in the same month of the same year. The largest parcel of land to be potentially disturbed at any one facility under Alternative B could occur at Facility H and is approximately 1,200 square feet which represents approximately 51 percent of the total area to be disturbed under Alternative B. Assuming that all three facilities conduct overlapping site preparation activities as a worst-case, then the potential peak area that could be disturbed at any one time would be 2,340 square feet under Alternative B.

In any case, the amount of area to be disturbed is small such that one backhoe should be sufficient for site preparation activities under Alternative B. Since one backhoe can trench approximately 0.1 acre per day or 4,356 square feet per day, earthmoving activities at Facility H would take approximately one day under Alternative B. Even if all three facilities conduct overlapping site preparation, earthmoving activities would take about the same amount of time since each plot space is relatively small (i.e., a ¼-acre plot or smaller) and there would be one backhoe in operation at each of the three facilities.

To comply with the dust suppression requirements in SCAQMD Rule 403 – Fugitive Dust, during site preparation activities, some water is expected to be used. For example, one water truck per affected facility may be needed for dust suppression activities during the initial site preparation/earth moving portion of the proposed project. One water truck can hold approximately 6,000 gallons for dust control and it can be refilled over the course of the day if more than 6,000 gallons is needed. By applying one gallon of water per square foot of disturbed

area, at a minimum of two times per day as required to minimize fugitive dust, the total amount of water expected to be used for dust suppression is approximately 4,680 gallons per day under Alternative B. On windy days, it may be necessary to conduct a third water application. Thus, the total peak amount of water that could be used for dust suppression is approximately 7,020 gallons per day under Alternative B. In any case, one water truck would be sufficient, but it would need to be refilled to accommodate the additional 1, 020 gallons of water needed for dust suppression on windy days.

Due to the need to quickly construct a proper foundation for the proposed control equipment, earth moving activities during site preparation is expected to be a short duration lasting from two to three days to no longer than one month per facility. As such, the corresponding dust control activities are also not expected to last longer than one month per facility. Further, water used for dust suppression does not have to be of potable quality, but can be recycled water.

For the three facilities that may undergo site preparation activities, recycled water is not currently available. However, recycled water availability is expected to expand to Facility J by Summer 2013[98]. Thus, if site preparation activities occur after Summer 2013 at Facility J, then recycled water may be available to supply the peak 1,500 gallons per day that may be needed for dust suppression at that location.

Instead of installing new equipment, one facility operator (Facility C) may choose to modify or upgrade their existing SOx control equipment. In these cases, site preparation activities are not expected because the existing foundation and the existing equipment are expected to be reused in its current location and current plot space. Therefore, no water for dust suppression purposes is expected to be needed for any construction upgrades to existing SOx control equipment at Facility C.

Once constructed, but prior to operation, additional water is expected to be used to hydrostatically (pressure) test all vessels and pipelines to ensure each structure's integrity and wastewater may be created during the testing. Pressure testing is typically a one-time event, unless a leak is found. Similar to dust suppression, water used for pressure testing does not have to be of potable quality, but can be recycled water.

Even though the potential increase in water use under Alternative B is below the SCAQMD's five million gallons per day significance threshold for total water, it may be helpful to consider other criteria for evaluating what would be considered a substantial use of potable water, especially since California is in a State of Emergency for Drought. For example, CEQA Guidelines §15155 – City or County Consultation With Water Agencies, defines a "water demand" project in several ways. While the criteria for defining water demand are not significance thresholds per se, the criteria can provide some insight as to how city or county lead agencies evaluate water demand impacts. Most of the criteria in this part of the CEQA Guidelines do not have a numerical criterion or direct methodology to correlate the criteria in

[98] Future access to recycled water for these five facilities is dependent upon the completion of the Harbor Refineries Recycled Water Pipeline Project (HRRWPP) by Summer 2013 (SCH No. 2008121093, certified on October 20, 2009). The HRRWPP will conserve potable water and instead produce and convey recycled water to multiple industrial and irrigation customers in the Los Angeles Harbor area (http://www.ladwp.com/ladwp/cms/ladwp011486.jsp). Proponents of the HRRWPP are working with each of the affected facilities to negotiate construction of a new water conveyance at their site in order to tie-into the recycled water pipeline.

terms of gallons per day for use as a significance threshold specific to potable water use. However, CEQA Guidelines §15155 (a)(1)(G) defines a water demand project as: "A project that would demand an amount of water equivalent to, or greater than, the amount of water required by a 500 dwelling unit project." To estimate what this means in terms of quantifying how much potable water could be used by a 500 dwelling unit (DU) project, the California Department of Water resources relies on a conversion factor range of 0.3 to 0.5 acre-feet of potable water per year per DU as shown in the following calculation[99]:

$$(500\ \text{DUs}) \times \frac{(0.3 - 0.5\ \text{acre-feet/year})}{(1\ \text{DU})} \times \frac{(325{,}851\ \text{gallons})}{(1\ \text{acre-foot})} \times \frac{(1\ \text{year})}{(365\ \text{days})} = 133{,}911\ \text{gallons/day to } 223{,}186\ \text{gallons/day}$$

Thus, the amount of water that would be needed during construction for dust suppression and pressure testing activities: 1) would not be considered a substantial use of potable water since the amount of plot space that would undergo site preparation and dust suppression activities is so small and the peak amount of water needed for these activities is small; and 2) is substantially less than the overall water demand significance threshold of five million gallons per day. Further, watering activities for dust suppression and pressure-testing are temporary and occur on a short-term basis. For these reasons, less than significant water demand/water use impacts are expected during construction of the proposed project.

Construction Water Quality

Any wastewater generated from pressure testing is expected to flow to each affected facility's wastewater treatment or collection system and recycled or discharged after treatment with process wastewater. Thus, wastewater generation from pressure testing activities is not expected to affect groundwater quality. Further, the volume of wastewater that will be generated from pressure testing is expected to be minimal and within the capacity of each facility's wastewater treatment and collection systems.

With the total amount of disturbed area for all of the facilities combined is estimated to be 2,340 square feet (0.05 acre) under Alternative B with the peak amount of area to be disturbed at Facility H at 1,230 square feet, a NPDES General Permit for Storm Water Discharges Associated with Construction Activity, also referred to as a Storm Water Construction Permit, would not be required for any of the affected facilities. Because Alternative B is expected to disturb substantially less than one acre per facility, on-site collection of storm water in each facility's storm water collection system is expected to be about the same as the amount currently collected. Therefore, no significant impacts are expected from storm water during construction.

Construction Conclusion

In summary, less than significant adverse water demand and wastewater impacts are expected during construction of Alternative B.

Operational Water Demand

Table 5-37 quantifies the potential increases in operational water use and wastewater generation that may occur as a result of installing new or upgrading existing SOx controls under Alternative B. If all of the proposed control technologies are installed or upgraded, the potential increase in water use is estimated to be approximately 0.12 MMgal/day under Alternative B. Further, if all

[99] Draft Guidebook for Implementation of Senate Bill 610 and Senate Bill 221 of 2001 to assist water suppliers, cities, and counties in integrating water and land use planning, California Department of Water Resources, September 2002, p.3

of the proposed control technologies are installed or upgraded, the potential increase in wastewater generated would be approximately 0.04 MMgal/day under Alternative B. Hydrology and water quality impacts from Alternative B are discussed in detail in the following sections.

Table 5-37
Alternative B: Potential Increases in Operational Water Demand and Wastewater Generation

Main Equipment	Proposed Control Technology That Utilizes Water	No. of Facilities to Install or Upgrade Controls	No. of Units Expected to Be Installed or Upgraded	Potential Increase in Operational Water Demand (gal/day)	Potential Increase in Wastewater Generation (gal/day)
FCCU	WGS	0	0	0	0
SRU/TGU	WGS	0	0	0	0
Refinery Boilers/Heaters	FGT	0	0	0	0
Coke Calciner	WGS	1	1	40,896	16,992
Glass Melting Furnaces	WGS	1	2	58,464	12,877
Sulfuric Acid	WGS	1	1	19,589	10,800
Sulfuric Acid	Upgrade Existing Cansolv Unit	1	1	6,336	0[1]
Cement Kilns	DGS	0	0	0	0
		Total	**5**	**125,285**	**40,669**

[1] More water (as steam) is required to complete the upgrade. However, the steam is evaporated during the process so there is no wastewater stream generated.

As summarized in Table 5-38, each affected facility provided their water demand baseline; these water usage rates were compared to each facility's estimated potential increase in water demand that may result from implementing Alternative B. The peak percentage increase from baseline levels when compared to Alternative B was approximately 45 percent (Facility I) but most of the affected facilities have a potential increase in water demand from one to four percent above each facility's baseline. The overall increase in water demand under Alternative B is approximately 1.28 percent above the total water use baseline for all of the affected facilities combined.

To have a better understanding about the availability of water and the source (i.e., potable versus non-potable recycled or industrial-use groundwater), SCAQMD staff contacted each supplier of water used for industrial applications for each of the affected facilities[100], and all of the suppliers indicated that they would be able to accommodate the additional operational water demand if the proposed project goes forward. In addition, each water supplier specified whether the additional water to be supplied will be recycled water or potable water. In the case of recycled water, the water supplier indicated whether the recycled water is currently available or whether it would be available in the future pursuant to the aforementioned HRRWPP project.

[100] Facility K is the only facility that does not purchase water for its industrial operations; instead, the industrial-use water (non-potable) is supplied by the facility-owned wells.

Table 5-38
Alternative B: Potential Increases in Operational Water Demand per Facility

Facility ID	Proposed Control Technology	Potential Increase in Water Use (MMgal/day)	Current Facility Water Use (MMgal/day)	Percentage Increase Above Baseline
A	Not applicable to Alternative B	0	10.75	0%
B	Not applicable to Alternative B	0	12.50	0%
C	1 Upgrade to Existing Cansolv Unit/Sulfuric Acid (modified)	0.006	7.85	0.08%
D	Not applicable to Alternative B	0	10.32	0%
E	Not applicable to Alternative B	0	5.76	0%
F	Not applicable to Alternative B	0	2.50	0%
G	Not applicable to Alternative B	0	2.88	0%
H	1 WGS for calciner (new)	0.041	1.08	3.79%
I	2 WGSs for glass melting furnaces (new)	0.058	0.13	44.62%
J	1 WGS for sulfuric acid unit (new)	0.020	0.73	2.74%
K	Not applicable to Alternative B	0	3.29	0%
	TOTAL	**0.125**	**9.79***	**1.28%***

* This total is based on the current facility water use for only those facilities affected by Alternative B (e.g., Facilities C, H, I and J).

As part of making the determination if water supplies will be sufficient for Alternative B, the availability of recycled or industrial-use groundwater is an important factor. Seven facilities are expected to have either increased access (e.g., Facilities A, B and D) or new future access (e.g., Facilities C, E, F and J) to recycled water upon completion of the HRRWPP[101], but of these, only Facilities C and J would be affected by Alternative B . The HRRWPP is a project shared by the LADWP and WBMWD to conserve potable water and instead produce and convey recycled water to multiple industrial and irrigation customers in the Los Angeles Harbor area. Construction of the HRRWPP began on October 26, 2009 and is estimated to be completed by Summer 2013. However, even if the pipeline and meter is installed, these facilities will need to make modifications to handle the potential increase in recycled water or install the water conveyance infrastructure piping to tie-in to the recycled water pipeline.

Table 5-39 identifies the amount and availability status of using non-potable[102] and potable water to supply the potential increased water use under Alternative B. The amount of non-potable water that can currently be used under Alternative B plus the future availability of non-potable water (to be available beginning Summer 2013) is 25,925 gallons per day. Of the proposed increase of total water at 125,285 gallons per day under Alternative B, 21 percent may be supplied by recycled or non-potable water. The remaining amount of increased potential water demand under Alternative B is estimated to be 79 percent or 99,360 gallons per day and is expected to be satisfied by potable water.

[101] The future availability of recycled water applies to certain facilities that do not currently have access to obtain recycled water for their processes but that will have access after completion of the LADWP's HRRWPP project (certified on October 20, 2009) by Summer 2013 (http://www.ladwp.com/ladwp/cms/ladwp011486.jsp). In addition, future access to recycled water is contingent upon each facility within the HRRWPP project area constructing a new water conveyance at their site in order to tie-into the recycled water pipeline.

[102] Non-potable water can be either recycled water or industrial-use well water.

Table 5-39
Alternative B: Potential Increases in Non-Potable and Potable Water Use

Main Equipment	Proposed Control Technology That Utilizes Water	Potentially Available Non-Potable Water Use		Potentially Available Potable Water Use (gal/day)	Total Potential Increase in Water Use (gal/day)
		Current [1] (gal/day)	Future[2] (gal/day)		
FCCU	WGS	0	0	0	0
SRU/TGU	WGS	0	0	0	0
Refinery Boilers/Heaters	FGT	0	0	0	0
Coke Calciner	WGS	0	0	40,896	40,896
Glass Melting Furnaces	WGS	0	0	58,464	58,464
Sulfuric Acid	WGS	19,589	0	0	19,589
Sulfuric Acid	Upgrade Existing Cansolv Unit	0	6,336	0	6,336
Cement Kilns	DGS	0	0	0	0
	Total	**19,589**	**6,336**	**99,360**	**125,285**

[1] The current availability of non-potable water values assumes that the facilities which currently obtain recycled or industrial-use groundwater for their processes will continue to do so if there is a need to increase water use as part of the proposed project.

[2] The future availability of non-potable water values applies to certain facilities that do not currently have access to obtain recycled or industrial-use groundwater for their processes but that will have access after completion of the LADWP's HRRWPP project by Summer 2013.

Table 5-40 summarizes the projected increases of potable water, recycled water (both current and future availability) and industrial-use groundwater that is estimated to implement Alternative B at the affected facilities.

Table 5-40
Alternative B: Distribution of Projected Water Demand by Water Type

Type of Water	Projected Increase in Water Use (gal/day)	Percent of Total Water Demand
Potable	99,360	79%
Recycled (non-potable)	25,925	21%
Industrial-Use Groundwater (non-potable)	0	0%
TOTAL	**125,285**	**100%**

Alternative B has been shown to potentially increase total water demand by approximately 125,285 gallons per day and 79 percent of this total water demand would need to be supplied by potable water because the facilities that would be affected by Alternative B (Facilities C, H, I and J), only Facilities C and J have access to non-potable water. Also, the potential increases in total water demand rely on the future availability of recycled water for Facility C.

Thus, the amount of water that would qualify as a water demand project can be adjusted to separate the potable water from the current and future uses of recycled water and industrial-use groundwater needed for Alternative B. To establish whether Alternative B qualifies as a water demand project, the potential increase in water use can be interpreted to mean the potential increase of potable water only (in this case, 99,360 gallons per day). Since the projected increase of potable water and total water would be less than the estimated range of water that would be

needed for a 500 DU project (e.g., 133,911 to 223,186 gallons per day), Alternative B would not qualify as a water demand project.

However, the projections for new or increased future access to recycled water are 6,336 gallons per day under Alternative B and the availability of future access to recycled water is not guaranteed. In the event that the future access to recycled water does not occur as planned by Summer 2013 in accordance with the HRRWPP, the potential increase in potable water needed for Alternative B would need to be adjusted to include the amount of future recycled water. As such, the amount of potable water demand could increase to 105,696 gallons per day under Alternative B. In the event that future access to recycled water does not occur as planned, the distribution between potable and recycled water demand shifts as summarized in Table 5-41.

Table 5-41
Alternative B: Adjusted Distribution of Projected Water Demand by Water Type if Future Supplies of Recycled Water Are Not Available

Type of Water	Adjusted Projected Increase in Water Use (gal/day)	Percent of Total Water Demand
Potable	105,696	84%
Recycled (non-potable)	19,589	16%
Industrial-Use Groundwater (non-potable)	0	0%
TOTAL	**125,285**	**100%**

Under Alternative B, the adjusted estimate for increased potable water demand would be 105,696 gallons per day, which is below the minimum amount of potable water needed to qualify for as a water demand project per the 500 DU calculations (e.g., 133,911 gallons per day). Thus, for this reason, Alternative B would not qualify as a water demand project and as such, is expected to contribute to less than significant adverse water demand impacts.

Lastly, to investigate whether the existing water supply has the capacity to meet the increased water demand of Alternative B, SCAQMD staff has been coordinating with various water suppliers (e.g., LADWP, MWD, WBMWD, Long Beach Water Department, City of Vernon etc.) to the affected facilities. Water suppliers for all of the facilities that either currently use recycled water or are expected to have future use of recycled water have indicated that there will be sufficient supply of recycled water for Alternative B. In addition, the water suppliers for Facilities H and I have indicated that they can supply the estimated additional potable water needed for operating WGSs under Alternative B.

Water Quality

As summarized in Table 5-42, each affected facility provided their wastewater discharge limits and these limits were compared to each facility's estimated potential increase in wastewater that may result from implementing Alternative B. The peak percentage increase from baseline levels is approximately nine percent (Facility H) under Alternative B. An increase of 25 percent would trigger a permit revision and would be considered a significant adverse wastewater impact. Since all of the affected facilities have been shown under Alternative B to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated under Alternative B. Thus, the operational impacts of Alternative B on

each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant.

Changes to each affected facility's storm water collection systems are expected to be less than significant since most of the changes will occur within existing units (i.e., installing control equipment on existing equipment or upgrading existing control equipment). Further, typically most of the areas likely to be affected by Alternative B are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each facility's current wastewater collection or treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions.

Alternative B is expected to involve construction activities located within the confines of existing facilities and does not include the construction of any new housing so it would not place new housing within a 100-year flood hazard area. It is likely that most affected facilities are not located within a 100-year flood hazard area. Any affected facilities that may be located in a 100-year flood area could impede or redirect 100-year flood flows, but this would be considered part of the existing setting and not an effect of Alternative B. Further, Alternative B would not require locating new facilities within a flood zone, so it is not expected to expose people or property to any known water-related flood hazards.

Table 5-42
Alternative B: Potential Increases in Wastewater Generation per Facility

Facility ID	Proposed Control Technology	Potential Increase in Wastewater Generation (MMgal/day)	Wastewater Permit Discharge Limit[1] (MMgal/day)	Percentage Increase Above Discharge Limit	Greater than 25% Increase? (Exceeds CEQA Significance Threshold?)
A	Not applicable to Alternative B	0	7.5	0%	NO
B	Not applicable to Alternative B	0	8.8	0%	NO
C	1 Upgrade to Existing Cansolv Unit (modified)	0	7.6	0%	NO
D	Not applicable to Alternative B	0	15	0%	NO
E	Not applicable to Alternative B	0	1.1	0%	NO
F	Not applicable to Alternative B	0	0.18	0%	NO
G	Not applicable to Alternative B	0	2.88	0%	NO
H	1 WGS for calciner (new)	0.017	0.18	9.44%	NO
I	2 WGSs for glass melting furnaces (new)	0.013	0.36	3.58%	NO
J	1 WGS for sulfuric acid unit (new)	0.011	0.21	5.14%	NO
K	2 DGSs for cement kilns (new)	0	No Limit	0%	NO
		0.041	**0.75**[2]	**5.47%**[2]	

[1] Wastewater limits were obtained from each facility's wastewater permit(s). For any facility that has multiple discharge limits (i.e. dry weather, wet weather, etc.), the most conservative limit will be used for the purpose of this comparison.

[2] This total is based on the current facility wastewater permit for only those facilities with wastewater impacts affected by Alternative B (e.g., Facilities H, I and J).

Alternative B does not require construction of new facilities in areas that could be affected by tsunamis. Of the facilities affected by Alternative B, some are located near the Ports of Long Beach and Los Angeles. However, the port areas are protected from tsunamis by the construction of breakwaters. Construction of breakwaters combined with the distance of each facility from the water is expected to minimize the potential impacts of a tsunami or seiche so that no significant impacts are expected. Alternative B does not require the construction of facilities in areas that are susceptible to mudflows (e.g., hillside or slope areas). Existing affected facilities that are currently located on hillsides or slope areas may be susceptible to mudflow, but this would be considered part of the existing setting. As a result, Alternative B is not expected to generate significant adverse mudflow impacts.

Lastly, Alternative B is not expected to significantly adversely affect the quantity or quality of groundwater in the area of each affected facility. No significant adverse impacts to groundwater quality are expected from Alternative B because: 1) wastewater will continue to be collected and treated in each of the affected facility's wastewater treatment systems or in compliance with the current wastewater discharge permits, as applicable; 2) no underground storage tanks are expected to be constructed as part of the proposed project; 3) containment berms will be required or may already exist around the new or modified units to minimize the potential for spills to contaminate soil and groundwater; and, 4) any new storage tanks that may be proposed will be required to comply with BACT and other safety requirements such as double bottom and monitoring requirements.

Water Demand and Water Quality Conclusion

The water demand impacts that may result from Alternative B have been shown to require approximately 125,285 gallons per day of total water with approximately 21 percent to be satisfied with current and future supplies of recycled water and the remaining 79 percent to be supplied by potable water. However, if future access to recycled water does not occur, then approximately 16 percent of the total water demand is expected to be satisfied with current supplies of recycled water and the remaining 84 percent is expected to be supplied by potable water under Alternative B.

Based on the preceding analysis, Alternative B is not expected to exceed SCAQMD's significance threshold of five million gallons of total water per day. Whether future supplies of recycled water become available or not, Alternative B is not expected to require a substantial amount of potable water as calculated pursuant to the water demand project criteria. Further, the water suppliers have indicated that there will be an adequate supply of water (current and future supplies of recycled water plus potable water) for Alternative B. Therefore, the water demand impacts for Alternative B are concluded to be less than significant.

Based on the aforementioned considerations, the potential groundwater, wastewater discharge and storm water discharge impacts that may result from Alternative B are expected to be less than significant. Less than significant adverse impacts associated with water demand and water quality are expected from Alternative B, so no mitigation measures are required. Because the water demand and water quality impacts from Alternative B do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative water demand and water quality impacts.

Alternative C – Intermediate SOx Reductions

Alternative C would impose the same SOx limits on fewer equipment/source categories when compared to both Options 1 and 2 of the proposed project. Specifically, five equipment/source categories comprise Alternative C: FCCUs, sulfuric acid manufacturing, coke calciner, glass melting furnaces, and cement kilns. Like the proposed project, there are two SOx control approaches that can be applied to FCCUs under Alternative C. For this reason, Alternative C has been bifurcated into two options: Option 1 assumes that WGSs will be the control approach for FCCUs; and, Option 2 assumes that SOx reducing additives will be the control approach for FCCUs. The remaining source categories and their respective control approaches applicable to Alternative C will be the same for both Option 1 and Option 2.

Under Alternative C, less add-on control equipment (i.e., eight WGSs plus two DGSs under Option 1 and four WGSs plus two DGSs under Option 2) would be expected to be installed under Alternative C and as such, less water demand and wastewater generation would occur when compared to the proposed project. Further, the reduced number of add-on control equipment to be installed under Alternative C - Option 2 can be attributed to the assumption that SOx reduction catalysts could be utilized in the FCCUs. Like the proposed project, both Options 1 and 2 of Alternative C would need additional water and would generate additional wastewater for installation and operation activities associated with the add-on control equipment.

The following analysis will demonstrate that the projected increases in water demand and wastewater generation associated with Alternative C will be less than significant because the amount of additional water demand and wastewater generation associated with the installation and operation of the new SOx controls are below the applicable hydrology and water quality significance criteria. While fewer WGSs would be installed under Alternative C for both Options 1 and 2, adverse hydrology and water quality impacts are expected to occur but they will be less than the proposed project.

Water demand and wastewater generation information as it relates to construction and operational activities under Alternative C was derived as part of the hydrology and water quality analysis in Chapter 4 and the calculations are shown in Appendix B of this ~~Draft~~ Final PEA.

Construction Water Demand

Implementation of Alternative C is expected to result in construction activities associated with installing new or modifying existing SOx control equipment at the affected facilities, which are complex, well-established and mostly paved, industrial facilities. Depending on the proposed location within each facility's boundaries for the siting of any new control equipment that may be installed as a result of implementing Alternative C, construction activities such as digging, earthmoving, grading, slab pouring, or paving could occur if the proposed site for the new equipment is not suitable in its present form (e.g., graded with a foundation slab). Tables 5-43 and 5-44 contain a summary of the estimates of plot space needed per facility for Option 1 and Option 2 of Alternative C.

Based on the consultant's surveys of the affected facilities, if all affected facilities conduct site preparation activities, the total amount of disturbed area for all of the facilities combined is estimated to be 31,790 square feet (0.7 acre) for Option 1 and 24,640 square feet (0.6 acre) for Option 2. However, even if all affected facilities intend to conduct site preparation, not much overlap of site preparation activities would be expected since there are several years between the proposed rule amendment date (2010) and the proposed compliance date (January 1, 2019) and

because the plot spaces are relatively small. Further, depending on the scale, site preparation typically can take anywhere from two weeks to one month. Therefore, it is unlikely that all affected facilities will do site preparation both in the same month of the same year. The largest parcel of land to be potentially disturbed is 6,000 square feet at three facilities (Facilities C, D and G) for both Options 1 and 2 of Alternative C and which represents approximately 19 percent of the total area to be disturbed for Option 1 and 24 percent of the total area to be disturbed for Option 2. Consistent with the assumption that, as a worst-case, up to four facilities conduct overlapping site preparation activities, then the potential peak area that could be disturbed at any one time would be 22,000 square feet for either Option 1 or 2.

Under either option, the amount of area to be disturbed is relatively small such that one backhoe should be sufficient for site preparation activities. Since one backhoe can trench approximately 0.1 acre per day or 4,356 square feet per day, earthmoving activities at either Facility C, D or G would take approximately two days for either Option 1 or Option 2 under Alternative C. Even if four facilities conduct overlapping site preparation, earthmoving activities would take about the same amount of time since each plot space is relatively small (i.e., a ¼-acre plot or smaller) and there would be one backhoe in operation at each of the four facilities.

Construction Water Demand

To comply with the dust suppression requirements in SCAQMD Rule 403 – Fugitive Dust, during site preparation activities, some water is expected to be used. For example, one water truck per affected facility may be needed for dust suppression activities during the initial site preparation/earth moving portion of the proposed project. One water truck can hold approximately 6,000 gallons for dust control and it can be refilled over the course of the day if more than 6,000 gallons is needed. By applying one gallon of water per square foot of disturbed area, at a minimum of two times per day as required to minimize fugitive dust, the total amount of water expected to be used for dust suppression is approximately 8,712 gallons per facility per day. ~~can range from 1,000 gallons per day up to 12,000 gallons per day, depending on the facility.~~ However, if four facilities with the largest plot spaces disturbed conduct overlapping watering, then the maximum amount of water that could be used for site preparation is 34,848 ~~44,000~~ gallons per day. On windy days, it may be necessary to conduct a third water application. Thus, the total peak amount of water that could be used for dust suppression can range from 1,500 gallons per day to 13,068 ~~18,000~~ gallons per day, depending on the facility. Again, if the four

facilities with the largest plot spaces disturbed conduct overlapping watering, at a watering rate of three applications per day, then the peak amount of water that could be used for site preparation is 52,272 ~~66,000~~ gallons per day.

Due to the need to quickly construct a proper foundation for the proposed control equipment, earth moving activities during site preparation are expected to be of a short duration lasting from two to three days to no longer than one month per facility. As such, the corresponding dust control activities are also not expected to last longer than one month per facility. Further, water used for dust suppression does not have to be of potable quality, but can be recycled water. Recycled water is currently available at three of the affected facilities and non-potable industrial-use groundwater is currently available at one additional facility. Additional recycled water availability is expected to expand to five other facilities by Summer 2013[103].

Since the earliest year when construction activities could begin would be in 2012, eight facilities are expected to have access to recycled or industrial-use groundwater for use during site preparation. There are three facilities (Facilities G, H and I) that do not currently have access to recycled or industrial-use groundwater and are not expected to have future access in 2012 or later. However, the amount of site preparation that would need to occur at these three facilities is expected to be about 7,840 square feet which would require approximately 15,680 gallons of water (at a watering rate of twice each day) to 23,520 gallons of water (at a watering rate of three times each day) for dust suppression activities during windy days.

Instead of installing new equipment, there are a few facility operators that may choose to modify or upgrade their existing SOx control equipment. In these cases, site preparation activities are not expected because the existing foundation and the existing equipment are expected to be reused in its current location and current plot space. Therefore, no water for dust suppression purposes is expected to be needed for any construction upgrades to existing SOx control equipment.

Once constructed, but prior to operation, additional water is expected to be used to hydrostatically (pressure) test all vessels and pipelines to ensure each structure's integrity and wastewater may be created during the testing. Pressure testing is typically a one-time event, unless a leak is found. Similar to dust suppression, water used for pressure testing does not have to be of potable quality, but can be recycled water.

Even though the potential increase in water use for both Option 1 and Option 2 of Alternative C is below the SCAQMD's five million gallons per day significance threshold for total water, it may be helpful to consider other criteria for evaluating what would be considered a substantial use of potable water, especially since California is in a State of Emergency for Drought. For example, CEQA Guidelines §15155 – City or County Consultation With Water Agencies, defines a "water demand" project in several ways. While the criteria for defining water demand

[103] Future access to recycled water for these five facilities is dependent upon the completion of the Harbor Refineries
Recycled Water Pipeline Project (HRRWPP) by Summer 2013 (SCH No. 2008121093, certified on October 20, 2009). The HRRWPP will conserve potable water and instead produce and convey recycled water to multiple industrial and irrigation customers in the Los Angeles Harbor area (http://www.ladwp.com/ladwp/cms/ladwp011486.jsp). Proponents of the HRRWPP are working with each of the affected facilities to negotiate construction of a new water conveyance at their site in order to tie-into the recycled water pipeline.

are not significance thresholds per se, the criteria can provide some insight as to how city or county lead agencies evaluate water demand impacts. Most of the criteria in this part of the CEQA Guidelines do not have a numerical criterion or direct methodology to correlate the criteria in terms of gallons per day for use as a significance threshold specific to potable water use. However, CEQA Guidelines §15155 (a)(1)(G) defines a water demand project as: "A project that would demand an amount of water equivalent to, or greater than, the amount of water required by a 500 dwelling unit project." To estimate what this means in terms of quantifying how much potable water could be used by a 500 dwelling unit (DU) project, the California Department of Water resources relies on a conversion factor range of 0.3 to 0.5 acre-feet of potable water per year per DU as shown in the following calculation[104]:

$$(500\ \text{DUs}) \times \frac{(0.3 - 0.5\ \text{acre-feet/year})}{(1\ \text{DU})} \times \frac{(325{,}851\ \text{gallons})}{(1\ \text{acre-foot})} \times \frac{(1\ \text{year})}{(365\ \text{days})} = 133{,}911\ \text{gallons/day to } 223{,}186\ \text{gallons/day}$$

Thus, the amount of water that would be needed during construction for dust suppression and pressure testing activities: 1) would not be considered a substantial use of potable water since several facilities are currently using or will have future access to recycled water; and 2) is less than the overall water demand significance threshold of five million gallons per day. Further, watering activities for dust suppression and pressure-testing are temporary and occur on a short-term basis. For these reasons, less than significant water demand/water use impacts are expected during construction of the proposed project.

Construction Water Quality

Any wastewater generated from pressure testing is expected to flow to each affected facility's wastewater treatment or collection system and recycled or discharged after treatment with process wastewater. Thus, wastewater generation from pressure testing activities is not expected to affect groundwater quality. Further, the volume of wastewater that will be generated from pressure testing is expected to be minimal and within the capacity of each facility's wastewater treatment and collection systems.

Further, because the total amount of disturbed area for all of the facilities combined is estimated to be 31,790 square feet (0.7 acre) for Option 1 and 24,640 square feet (0.6 acre) for Option 2 with the peak amount of area to be disturbed at Facilities C, D and G at 6,000 square feet each, the proposed construction activities will disturb less than 0.13 acre under Option 1 and 0.16 acre under Option 2 at each of the remaining facilities. This means that a NPDES *General Permit for Storm Water Discharges Associated with Construction Activity*, also referred to as a Storm Water Construction Permit, would not be required for any of the affected facilities. Because Alternative C is expected to disturb substantially less than one acre total, on-site collection of storm water in each facility's storm water collection system is expected to be about the same as the amount currently collected. Therefore, no significant impacts are expected from storm water during construction.

Construction Conclusion

In summary, less than significant adverse water demand and wastewater impacts are expected during construction of both Options 1 and 2 of Alternative C.

[104] Draft Guidebook for Implementation of Senate Bill 610 and Senate Bill 221 of 2001 to assist water suppliers, cities, and counties in integrating water and land use planning, California Department of Water Resources, September 2002, p.3

Operational Water Demand

Tables 5-45 and 5-46 quantify the potential increases in operational water use and wastewater generation as a result of installing new or upgrading existing SOx controls to comply with Options 1 and 2 of Alternative C, respectively. If all of the proposed control technologies are installed or upgraded, the potential increase in water use is estimated to be approximately 0.5 MMgal/day under Option 1 and 0.3 MMgal/day under Option 2. Further, if all of the proposed control technologies are installed or upgraded, the potential increase in wastewater generated would be approximately 0.2 MMgal/day under Option1 and 0.09 MMgal/day under Option 2. Hydrology and water quality impacts from Alternative C are discussed in detail in the following sections.

Table 5-45
Alternative C - Option 1: Potential Increases in Operational Water Demand and Wastewater Generation

Main Equipment	**Proposed Control Technology**	**No. of Facilities to Install or Upgrade Controls**	**No. of Units Expected to Be Installed or Upgraded**	**Potential Increase in Operational Water Demand** (gal/day)	**Potential Increase in Wastewater Generation** (gal/day)
FCCU	WGS	4	4	241,096	112,329
SRU/TGU	WGS	0	0	0	0
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	5	5	52,055	46,575
Coke Calciner	WGS	1	1	40,896	16,992
Glass Melting Furnaces	WGS	1	2	58,464	12,877
Sulfuric Acid	WGS	1	1	19,589	10,800
Sulfuric Acid	Upgrade Existing Cansolv Unit	1	1	6,336	0[1]
Cement Kilns	DGS	1	2	110,685	0[2]
		Total	**16**	**529,121**	**199,573**

[1] More water (as steam) is required to complete the upgrade. However, the steam is evaporated during the process so there is no wastewater stream generated.

[2] All of the injected water is evaporated during the process so there is no wastewater stream generated.

Table 5-46
Alternative C - Option 2: Potential Increases in Operational Water Demand and Wastewater Generation

Main Equipment	Proposed Control Technology	No. of Facilities to Install or Upgrade Controls	No. of Units Expected to Be Installed or Upgraded	Potential Increase in Operational Water Demand (gal/day)	Potential Increase in Wastewater Generation (gal/day)
FCCU	SOx Reducing Catalyst	5	5	0	0
SRU/TGU	WGS	0	0	0	0
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	5	5	52,055	46,575
Coke Calciner	WGS	1	1	40,896	16,992

Sulfuric Acid	WGS	1	1	19,589	10,800
Sulfuric Acid	Upgrade Existing Cansolv Unit	1	1	6,336	0[1]
Cement Kilns	DGS	1	2	110,685	0[2]
		Total	**17**	**288,025**	**87,244**

[1] More water (as steam) is required to complete the upgrade. However, the steam is evaporated during the process so there is no wastewater stream generated.

[2] All of the injected water is evaporated during the process so there is no wastewater stream generated.

Water Demand

As summarized in Tables 5-47 and 5-48, each affected facility provided their water demand baseline and these water usage rates were compared to each facility's estimated potential increase in water demand that may result from implementing Option 1 or Option 2 of Alternative C. For both Option 1 and Option 2 under Alternative C, the peak percentage increase from baseline levels was approximately 45 percent (Facility I) but most of the affected facilities have a potential increase in water demand from less than one to four percent above each facility's baseline. The overall increase in water demand for Option 1 is 0.92 percent above the total water use baseline for all of the affected facilities combined. Similarly, the overall increase in water demand for Option 2 is 0.50 percent above the total water use baseline for all of the affected facilities combined.

Table 5-47
Alternative C - Option 1: Potential Increases in Operational Water Demand per Facility

To have a better understanding about the availability of water and the source (i.e., potable versus non-potable recycled or industrial-use groundwater), SCAQMD staff contacted each supplier of water used for industrial applications for each of the affected facilities[105], and all of the suppliers indicated that they would be able to accommodate the additional operational water demand if Alternative C goes forward. In addition, each water supplier specified whether the additional water to be supplied will be recycled water or potable water. In the case of recycled water, the water supplier indicated whether the recycled water is currently available or whether it would be available in the future pursuant to the aforementioned HRRWPP project.

As part of making the determination if water supplies will be sufficient for Alternative C, the availability of recycled or industrial-use groundwater is an important factor. Seven facilities are expected to have either increased access (e.g., Facilities A, B and D) or new future access (e.g., Facilities C, E, F and J) to recycled water upon completion of the HRRWPP[106]. The HRRWPP is a project shared by the LADWP and WBMWD to conserve potable water and instead produce and convey recycled water to multiple industrial and irrigation customers in the Los Angeles

[105] Facility K is the only facility that does not purchase water for its industrial operations; instead, the industrial-use water (non-potable) is supplied by the facility-owned wells.

[106] The future availability of recycled water applies to certain facilities that do not currently have access to obtain recycled water for their processes but that will have access after completion of the LADWP's HRRWPP project (certified on October 20, 2009) by Summer 2013 (http://www.ladwp.com/ladwp/cms/ladwp011486.jsp). In addition, future access to recycled water is contingent upon each facility within the HRRWPP project area constructing a new water conveyance at their site in order to tie-into the recycled water pipeline.

Harbor area. Construction of the HRRWPP began on October 26, 2009 and is estimated to be completed by Summer 2013. However, even if the pipeline and meter is installed, these facilities will need to make modifications to handle the potential increase in recycled water or install the water conveyance infrastructure piping to tie-in to the recycled water pipeline.

Tables 5-49 and 5-50 identify the amount and availability status of using non-potable[107] and potable water to supply the potential increased water use as a result of Option 1 and Option 2 of Alternative C, respectively. The amount of non-potable water that can currently be used under Option 1 of Alternative C plus the future availability of non-potable water by Summer 2013 is 429,761 gallons per day. Of the total proposed increase of 529,121 gallons per day under Alternative C - Option 1, 81 percent may be supplied by recycled or non-potable water. The remaining amount of increased potential water demand under Alternative C - Option 1 is estimated to be 19 percent or 99,360 gallons per day and is expected to be satisfied by potable water.

Similarly, the amount of non-potable water that can currently be used under Alternative C - Option 2 plus the future availability of non-potable water by Summer 2013 is 188,665 gallons per day. Of the total proposed increase of 288,025 gallons per day under Alternative C - Option 2, 65 percent may be supplied by recycled or non-potable water. The remaining amount of increased potential water demand under Alternative C - Option 2 is estimated to be 35 percent or 99,360 gallons per day and is expected to be satisfied by potable water.

Table 5-49
Alternative C - Option 1: Potential Increases in Non-Potable and Potable Water Use

Main Equipment	Proposed Control Technology	Potentially Available Non-Potable Water Use		Potentially Available Potable Water Use (gal/day)	Total Potential Increase in Water Use (gal/day)
		Current [1] (gal/day)	Future[2] (gal/day)		
FCCU	WGS	147,945	93,151	0	241,096
SRU/TGU	WGS	0	0	0	0
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	49,315	2,740	0	52,055
Coke Calciner	WGS	0	0	40,896	40,896
Glass Melting Furnaces	WGS	0	0	58,464	58,464
Sulfuric Acid Mfg.	WGS	19,589	0	0	19,589
Sulfuric Acid Mfg.	Upgrade Existing Cansolv Unit	0	6,336	0	6,336
Cement Kilns	DGS	110,685	0	0	110,685
	Total	**327,534**	**102,227**	**99,360**	**529,121**

[1] The current availability of non-potable water values assumes that the facilities which currently obtain recycled or industrial-use groundwater for their processes will continue to do so if there is a need to increase water use as part of the proposed project.

[2] The future availability of non-potable water values applies to certain facilities that do not currently have access to obtain recycled or industrial-use groundwater for their processes but that will have access after completion of the LADWP's HRRWPP project by Summer 2013.

[107] Non-potable water can be either recycled water or industrial-use well water.

Table 5-50
Alternative C - Option 2: Potential Increases in Non-Potable and Potable Water Use

Main Equipment	Proposed Control Technology	Potentially Available Non-Potable Water Use		Potentially Available Potable Water Use (gal/day)	Total Potential Increase in Water Use (gal/day)
		Current [1] (gal/day)	Future[2] (gal/day)		
FCCU	SOx Reducing Additive	0	0	0	0
SRU/TGU	WGS	0	0	0	0
Refinery Boilers/Heaters	FGT (Merox Treatment or Convert Amine Absorbers to Sulfinol)	49,315	2,740	0	52,055
Coke Calciner	WGS	0	0	40,896	40,896
Glass Melting Furnaces	WGS	0	0	58,464	58,464
Sulfuric Acid	WGS	19,589	0	0	19,589
Sulfuric Acid	Upgrade Existing Cansolv Unit	0	6,336	0	6,336
Cement Kilns	DGS	110,685	0	0	110,685
	Total	**179,589**	**9,076**	**99,360**	**288,025**

[1] The current availability of non-potable water values assumes that the facilities which currently obtain recycled or industrial-use groundwater for their processes will continue to do so if there is a need to increase water use as part of the proposed project.
[2] The future availability of non-potable water values applies to certain facilities that do not currently have access to obtain recycled or industrial-use groundwater for their processes but that will have access after completion of the LADWP's HRRWPP project by Summer 2013.

Table 5-51 summarizes the projected increases of potable water, recycled water (both current and future availability) and industrial-use groundwater that is estimated to implement both Option 1 and Option 2 of Alternative C at the affected facilities.

Table 5-51
Alternative C: Distribution of Projected Water Demand by Water Type

	Option 1		Option 2	
Type of Water	**Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**	**Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**
Potable	99,360	19%	99,360	35%
Recycled (non-potable)	305,377	58%	64,281	22%
Industrial-Use Groundwater (non-potable)	124,384	23%	124,384	43%
TOTAL	**529,121**	**100%**	**288,025**	**100%**

Option 1 of Alternative C has been shown to potentially increase total water demand by approximately 529,121 gallons per day and 19 percent or 99,360 gallons per day of the total water demand would need to be supplied by potable water. Similarly, Option 2 of Alternative C has been shown to potentially increase total water demand by approximately 288,025 gallons per day and 35 percent or 99,360 gallons per day of the total water demand would need to be supplied by potable water.

Thus, the amount of water that would qualify as a water demand project can be adjusted to separate the potable water from the current and future uses of recycled water and industrial-use groundwater needed for Alternative C. To establish whether Alternative C qualifies as a water demand project, the potential increase in water use can be interpreted to mean the potential increase of potable water only (in this case, 99,360 gallons per day for both Option 1 and Option 2). Since the projected increase of potable water would be less than the estimated range of water that would be needed for a 500 DU project (e.g., 133,911 to 223,186 gallons per day), neither Option 1 nor Option 2 of Alternative C would qualify as a water demand project.

However, the projections for new or increased future access to recycled water for Alternative C are 102,227 gallons per day under Option 1 and 9,076 gallons per day under Option 2 and the availability of future access to recycled water is not guaranteed. In the event that the future access to recycled water does not occur as planned by Summer 2013 in accordance with the HRRWPP, the potential increase in potable water needed for Alternative C would need to be adjusted to include the amount of future recycled water. As such, the amount of potable water demand for Alternative C could increase to 201,587 gallons per day under Option 1 and 108,436 gallons per day under Option 2. In the event that future access to recycled water does not occur as planned, the distribution between potable and recycled water demand shifts as summarized in Table 5-52.

Table 5-52
Alternative C: Adjusted Distribution of Projected Water Demand by Water Type if Future Supplies of Recycled Water Are Not Available

	Option 1		**Option 2**	
Type of Water	**Adjusted Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**	**Adjusted Projected Increase in Water Use** (gal/day)	**Percent of Total Water Demand**
Potable	201,587	38%	108,436	38%
Recycled (non-potable)	203,150	38%	55,205	19%
Industrial-Use Groundwater (non-potable)	124,384	24%	124,384	43%
TOTAL	**529,121**	**100%**	**288,025**	**100%**

The adjusted estimate for increased potable water demand for Alternative C under Option 1 at 201,587 gallons per day is within the range between 133,911 gallons per day and 223,186 gallons per day based on the 500 DU water demand calculations. By applying the 500 DU water demand criteria to use as a significance threshold for potable water demand, Option 1 of the Alternative C may qualify as a water demand project and thus, may result in significant adverse water demand impacts.

However, for Alternative C - Option 2, the adjusted estimate for increased potable water demand would be 108,436 gallons per day, which is below the minimum amount of potable water needed to qualify for as a water demand project per the 500 DU calculations (e.g., 133,911 gallons per day). Thus, for this reason, Option 2 of Alternative C is expected to contribute to less than significant adverse water demand impacts.

Lastly, to investigate whether the existing water supply has the capacity to meet the increased water demand of the proposed project, SCAQMD staff has been coordinating with various water suppliers (e.g., LADWP, MWD, WBMWD, Long Beach Water Department, City of Vernon etc.) to the affected facilities. Water suppliers for all of the facilities that either currently use recycled water or are expected to have future use of recycled water have indicated that there will be sufficient supply of recycled water for the proposed project. In addition, the water suppliers for Facilities G, H and I have indicated that they can supply the estimated additional potable water needed for operating WGSs. Lastly, Facility K operates its own groundwater wells to pump non-potable industrial-use groundwater for their day-to-day operations. Because Facility K's groundwater pumping permit does not limit the amount of water that can be pumped from the wells, any additional water needed to implement the proposed project is expected to be available.

Water Quality

As summarized in Tables 5-53 and 5-54, each affected facility provided their wastewater discharge limits and these limits were compared to each facility's estimated potential increase in wastewater that may result from implementing Option 1 and Option 2 of Alternative C, respectively. The peak percentage increase from baseline levels for Alternative C was approximately 12 percent (Facility F) under Option 1 and nine percent (Facility H) under Option 2. An increase of 25 percent would trigger a permit revision and would be considered a significant adverse wastewater impact. Since all of the affected facilities have been shown under both options of Alternative C to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated as a result of implementing Alternative C. Thus, the operational impacts of Alternative C on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant.

Changes to each affected facility's storm water collection systems are expected to be less than significant since most of the changes will occur within existing units (i.e., installing control equipment on existing equipment or upgrading existing control equipment). Further, typically most of the areas likely to be affected by Alternative C are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each facility's current wastewater collection or treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions.

Alternative C is expected to involve construction activities located within the confines of existing facilities and does not include the construction of any new housing so it would not place new housing within a 100-year flood hazard area. It is likely that most affected facilities are not located within a 100-year flood hazard area. Any affected facilities that may be located in a 100-year flood area could impede or redirect 100-year flood flows, but this would be considered part of the existing setting and not an effect of Alternative C. Further, Alternative C would not require locating new facilities within a flood zone, so it is not expected to expose people or property to any known water-related flood hazards.

Table 5-53
Alternative C - Option 1: Potential Increases in Wastewater Generation per Facility

Facility ID	Proposed Control Technology	Potential Increase in Wastewater Generation (MMgal/day)	Wastewater Permit Discharge Limit[1] (MMgal/day)	Percentage Increase Above Discharge Limit	Greater than 25% Increase? (Exceeds CEQA Significance Threshold?)

I	2 WGSs for glass melting furnaces (new)	**0.013**	0.36	3.58%	NO
J	1 WGS for sulfuric acid unit (new)	**0.011**	0.21	5.14%	NO
K	2 DGSs for cement kilns (new)	**0**	No Limit	0%	NO
		0.087	**43.81**	**0.20%**	

[1] Wastewater limits were obtained from each facility's wastewater permit(s). For any facility that has multiple discharge limits (i.e. dry weather, wet weather, etc.), the most conservative limit will be used for the purposes of this comparison.

Alternative C does not require construction of new facilities in areas that could be affected by tsunamis. Of the facilities affected by Alternative C, some are located near the Ports of Long Beach and Los Angeles. However, the port areas are protected from tsunamis by the construction of breakwaters. Construction of breakwaters combined with the distance of each facility from the water is expected to minimize the potential impacts of a tsunami or seiche so that no significant impacts are expected. Alternative C does not require construction of facilities in areas that are susceptible to mudflows (e.g., hillside or slope areas). Existing affected facilities that are currently located on hillsides or slope areas may be susceptible to mudflow, but this would be considered part of the existing setting. As a result, Alternative C is not expected to generate significant adverse mudflow impacts.

Lastly, Alternative C is not expected to significantly adversely affect the quantity or quality of groundwater in the area of each affected facility. No significant adverse impacts to groundwater quality are expected from Alternative C because: 1) wastewater will continue to be collected and treated in each of the affected facility's wastewater treatment systems or in compliance with the current wastewater discharge permits, as applicable; 2) no underground storage tanks are expected to be constructed as part of Alternative C; 3) containment berms will be required or may already exist around the new or modified units to minimize the potential for spills to contaminate soil and groundwater; and, 4) any new storage tanks that may be proposed will be required to comply with BACT and other safety requirements such as double bottom and monitoring requirements.

Water Demand and Water Quality Conclusion

The water demand impacts that may result from Alternative C have been shown to require approximately 529,121 gallons per day of total water under Option 1 and 288,025 gallons per day of total water under Option 2. Under Option 1 of Alternative C, approximately 58 percent of the total water demand is expected to be satisfied with current and future supplies of recycled water, 23 percent is expected to be supplied by industrial-use groundwater, and the remaining 19 percent is expected to be supplied by potable water. However, if future access to recycled water does not occur, then approximately 38 percent of the total water demand is expected to be satisfied with current supplies of recycled water, 24 percent is expected to be supplied by industrial-use groundwater, and the remaining 33 percent is expected to be supplied by potable water under Alternative C - Option 1.

Similarly under Alternative C - Option 2, approximately 22 percent of the total water demand is expected to be satisfied with current and future supplies of recycled water, 43 percent is expected to be supplied by industrial-use groundwater, and the remaining 35 percent is expected to be supplied by potable water. Again, if future access to recycled water does not occur, then approximately 19 percent of the total water demand is expected to be satisfied with current supplies of recycled water, 43 percent is expected to be supplied by industrial-use groundwater, and the remaining 38 percent is expected to be supplied by potable water under Alternative C - Option 2.

Based on the preceding analysis, neither Option 1 nor Option 2 of Alternative C is expected to exceed SCAQMD's significance threshold of five million gallons of total water per day. If future supplies of recycled water become available, neither Option 1 nor Option 2 of the proposed project is expected to require a substantial amount of potable water as calculated pursuant to the water demand project criteria. However, in the event that future supplies of recycled water do not become available, only the potable water demand under Option 1 may require a substantial amount of potable water as calculated pursuant to the water demand project criteria. Further, the water suppliers have indicated that there will be an adequate supply of water (current and future supplies of recycled water plus potable water) for Alternative C under both Option 1 and Option 2. Therefore, the water demand impacts are concluded to be significant for Alternative C - Option 1 and less than significant for Alternative C - Option 2.

Lastly, based on the aforementioned considerations, the potential groundwater, wastewater discharge and storm water discharge impacts that may result from both Option 1 and Option 2 of Alternative C are expected to be less than significant.

When compared to the proposed project, the water demand impacts from both Option 1 and Option 2 of Alternative C are similar, but less than what was analyzed for the proposed project. Thus, any mitigation measures applied to the proposed project will also be applied to Alternative C. Further since the proposed project was concluded to have cumulatively considerable water demand impacts, while less than the proposed project, Alternative C is also considered to have cumulatively considerable water demand impacts. Therefore, Alternative C is expected to generate significant adverse cumulative water demand impacts.

TRAFFIC AND TRANSPORTATION

Alternative A - No Project

The project-specific traffic and transportation impacts associated with the installation of multiple SOx control devices (e.g., WGSs and DGSs) or modifying existing controls would be eliminated under Alternative A, the no project alternative, since no construction activities would occur and no new equipment would be installed at any of the affected facilities that would need additional trips associated with construction workers, supply deliveries, and waste removal/hauling. Under Alternative A, the traffic and transportation impacts would remain unchanged from the existing setting and therefore, would be less than significant.

Alternative B – AQMP

Because Alternative B applies the same SOx emission reduction targets as the proposed project but to fewer equipment/source categories (i.e., sulfuric acid manufacturing, coke calciner, and glass melting furnace), less add-on control equipment will be installed (i.e., four WGSs) such that fewer trips would be associated with construction and operation activities. The following analysis will demonstrate that the projected increases in trips associated with Alternative B will be less than significant because the amount of peak daily trips needed to install and operate the new SOx controls was well below the applicable trips significance criteria. While fewer WGSs would be installed with fewer trips under Alternative B, adverse traffic and transportation impacts are expected to occur but they will be less than the proposed project.

Under Alternative B, construction activities resulting from implementing the proposed project may generate a slight, albeit temporary, increase in traffic in the areas of each affected facility associated with construction workers, construction equipment, and the delivery of construction materials. However, Alternative B is not expected to cause a significant increase in traffic relative to the existing traffic load and capacity of the street systems surrounding the affected facilities. Also, Alternative B is not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during construction as explained in the following paragraph.

As previously noted in the section that discusses "Air Quality," the maximum construction workforce during any six-month construction period is expected to be approximately 175 workers per facility. For a worst-case analysis under Alternative B, all four facilities may need a total of up to 700 workers, if they were assumed to undergo overlapping construction activities. Even if it is assumed that all 700 construction workers drive alone (which represents an average vehicle ridership equal to 1.0) not all of the workers would be driving to the same facility. It is unlikely that these vehicle trips would substantially affect the LOS at any intersection because the trips will be somewhat dispersed over a large area and the workers would not all arrive at the same site at the exactly the same time. Therefore, the work force at each affected facility is not

expected to significantly increase as a result of Alternative B. Further, the conclusion of no significant transportation impacts based on the workforce is consistent with the transportation analyses in the Environmental Impact Reports prepared for six refineries in accordance with the CARB Phase III Reformulated Gasoline requirements. Specifically, the number of construction workers for each of the six projects ranged from approximately 200 to 700 daily construction worker trips and each of these projects was concluded to have no significant transportation impacts.

The operation-related traffic will be primarily for deliveries of NaOH and for hauling away of solid waste to be recycled or disposed of in a Class III landfill. Table 5-55 contains a summary of the delivery and haul away distances and frequencies for these materials. Since NaOH is available from local suppliers within the District, a round-trip delivery distance of 50 miles was assumed. This distance is expected to be conservative as most suppliers may be located closer to the affected facilities. For solid waste disposal, facility operators will have three options: 1) disposal of solid waste in a landfill located within the District or recycling of solid waste at a cement plant located within the District (i.e., 162 round-trip miles); 2) recycling of solid waste at a cement plant located outside of the District but within California (i.e., 264 round-trip miles); and, 3) recycling of solid waste at a cement plant located outside of the District and outside of California (i.e., 400 round-trip miles). For a worst-case analysis of solid waste disposal trips, the maximum mileage of 400 round-trip miles was assumed.

Table 5-55
Alternative B: Delivery and Hauling Away Truck Types and Driving Distances

Substance	Travels as a:	Truck Type	Delivery Area	Peak Round-trip Mileage per Delivery	Delivery Status
NaOH (50% by weight)	Pre-mixed liquid	6,000 gallon tanker truck	Within SCAQMD	50	Increase
Solid Waste	Varies	25-ton Heavy-duty Truck	Within or Outside SCAQMD	1. 162 for in-District recycling or disposal; 2. 264 for out-of-District but in-state recycling; or, 3. 400 for out of state recycling (worst-case)	Increase

A summary of the estimated truck trips of these substances per facility is provided in Table 5-56.

Table 5-56
Alternative B: Potential Increases in Truck Trips per Facility

Facility ID	Proposed Control Technology	Substances Delivered (D) or Hauled Away (H)	Peak Daily Truck Trips (round trips/day)	Peak Daily Round Trip Driving Distance (miles/day)	Annual Truck Trips (round trips/year)	Annual Round Trip Driving Distance (miles/day)
C	1 Upgrade to Existing Cansolv Unit/Sulfuric Acid (modified)	None	**0**	**0**	**0**	**0**
		Subtotal: Facility C	**0**	**0**	**0**	**0**
H	1 WGS for calciner (new)	1. NaOH (D) 2. Solid Waste (H)	1 + 1 **2**	50 + 400 **450**	32 + 7 **39**	1,600 + 2,800 **4,400**
		Subtotal: Facility H	**2**	**450**	**39**	**4,400**
I	2 WGSs for glass melting furnaces (new)	1. NaOH (D) 2. Solid Waste (H)	1 + 1 **2**	50 + 133 **183**	8 + 1 **9**	400 + 133 **533**
		Subtotal: Facility I	**2**	**183**	**9**	**533**
J	1 WGS for sulfuric acid unit (new)	NaOH (D)	**1**	**50**	**13**	**650**
		Subtotal: Facility J	**1**	**50**	**13**	**650**
		ALTERNATIVE B TOTAL	**5**	**683**	**61**	**5,583**

The amount of peak daily truck trips associated with Alternative B is five. Since Alternative B is not expected to have an increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day, less than significant transportation impacts are expected from implementation of Alternative B. Further, taking into consideration the "worst-case" delivery and hauling transportation schedule, delivery and hauling trips associated with Alternative B are not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during operations. Thus, the projected increase of traffic due to construction and operational activities is expected to be minimal and thus, the traffic impacts are expected to be less than significant for Alternative B.

Though some of the facilities that will be affected by the proposed project are located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, actions that would be taken to comply with Alternative B, such as installing new air pollution control equipment, are not expected to significantly influence or alter air traffic patterns. Further, the size and type of air pollution control devices that would be installed would not be expected to affect navigable air space because they would not be substantially taller than other equipment at affected facilities. Thus, Alternative B would not result in a change in air traffic patterns, an increase in traffic levels or a change in location that results in substantial safety risks.

The siting of each existing affected facility is consistent with surrounding land uses and traffic/circulation in the surrounding areas of the affected facilities. Thus, Alternative B is not

expected to substantially increase traffic hazards or create incompatible uses at or adjacent to the affected facilities. Aside from the temporary effects due to a slight increase in truck traffic when facilities undergo construction activities, Alternative B is not expected to alter the existing long-term circulation patterns. Further, Alternative B is not expected to require a modification to circulation, thus, no long-term impacts on the traffic circulation system are expected to occur. Alternative B does not involve construction of any roadways, so there would be no increase in roadway design feature that could increase traffic hazards. Emergency access at each affected facility is not expected to be impacted by Alternative B. Further, each affected facility is expected to continue to maintain its existing emergency access gates.

Each affected facility will be expected to provide parking for the construction workers, as applicable, either on or within close proximity to each facility. No additional parking will be needed after completion of the construction phase because the work force at each facility is not expected to significantly increase as a result of Alternative B.

Lastly, construction and operation activities resulting from Alternative B are not expected to conflict with policies supporting alternative transportation since the proposed project does not involve or affect alternative transportation modes (e.g., bicycles or buses) because the construction and operation activities related to Alternative B will occur solely in existing industrial, commercial, and institutional areas. Based upon these considerations, significant transportation/traffic impacts are not expected from the implementation of Alternative B.

Alternative C – Intermediate SOx Reductions

Alternative C proposes the same SOx emission reduction targets as the proposed project for the following equipment/source categories: FCCUs, sulfuric acid manufacturing, coke calciner, glass melting furnace, and cement kilns. Like the proposed project, there are two SOx control approaches that can be applied to FCCUs under Alternative C. For this reason, Alternative C has been bifurcated into two options: Option 1 assumes that WGSs will be the control approach for FCCUs; and, Option 2 assumes that SOx reducing additives will be the control approach for FCCUs. The remaining source categories and their respective control approaches applicable to Alternative C will be the same for both Option 1 and Option 2. Less add-on control equipment would be expected to be installed (and less existing equipment modified) under Alternative C (i.e., eight WGSs plus two DGSs under Option 1 and four WGSs plus two DGSs under Option 2) in order to achieve the proposed SOx emission limits as compared to the proposed project (i.e., 11 WGSs plus two DGSs for Option 1 and seven WGSs plus to DGSs under Option 2).

The following analysis will demonstrate that the projected increases in trips associated with Alternative C will be less than significant because the amount of peak daily trips needed to install and operate the new SOx controls was well below the applicable trips significance criteria. While less equipment would be installed or modified with fewer trips under Alternative C, adverse traffic and transportation impacts are expected to occur but they will be less than the proposed project.

Construction activities resulting from implementing both options of Alternative C may generate a slight, albeit temporary, increase in traffic in the areas of each affected facility associated with construction workers, construction equipment, and the delivery of construction materials. However, neither option of Alternative C is expected to cause a significant increase in traffic relative to the existing traffic load and capacity of the street systems surrounding the affected facilities. Also, Alternative C is not expected to exceed, either individually or cumulatively, the

current LOS of the areas surrounding the affected facilities during construction as explained in the following paragraph.

As previously noted in the section that discusses "Air Quality," the maximum construction workforce during any six-month construction period is expected to be approximately 175 workers per facility. For a worst-case analysis, four facilities may need a total of up to 700 workers were assumed to undergo overlapping construction activities. Even if it is assumed that all 700 construction workers drive alone (which represents an average vehicle ridership equal to 1.0) not all of the workers would be driving to the same facility. It is unlikely that these vehicle trips would substantially affect the LOS at any intersection because the trips will be somewhat dispersed over a large area and the workers would not all arrive at the same site at exactly the same time. Therefore, the work force at each affected facility is not expected to significantly increase as a result of Alternative C. Further, the conclusion of no significant transportation impacts based on the workforce is consistent with the transportation analyses in the Environmental Impact Reports prepared for six refineries in accordance with the CARB Phase III Reformulated Gasoline requirements. Specifically, the number of construction workers for each of the six projects ranged from approximately 200 to 700 daily construction worker trips and each of these projects was concluded to have no significant transportation impacts.

The operation-related traffic will be primarily for deliveries of NaOH, SOx reducing additives, limestone, TG-10 blend, Sulfinol, Merox catalyst, and elemental sulfur and for hauling away of solid waste to be recycled or disposed of in a Class III landfill. Table 5-57 contains a summary of the delivery and haul away distances and frequencies for each substance that is associated with Alternative C. Of the substances listed for deliveries, all but four are available from local suppliers within the District. For the local suppliers, a round-trip delivery distance of 50 miles was assumed. This distance is expected to be conservative as most suppliers are located closer to the affected facilities. However, suppliers for SOx Reducing Additives, Merox Catalyst, TG-10 and Sulfinol are all located out of state. Thus, deliveries of these materials are trucked into the District from out of state and the delivery mileage assumptions reflect the round-trip distance from the state line, either at the Arizona/California border (e.g., 400 miles) or the Nevada/California border (e.g., 500 miles). For solid waste disposal, facility operators will have three options: 1) disposal of solid waste in a landfill located within the District or recycling of solid waste at a cement plant located within the District (e.g., 162 round-trip miles); 2) recycling of solid waste at a cement plant located outside of the District but within California (e.g., 264 round-trip miles); and, 3) recycling of solid waste at a cement plant located outside of the District and outside of California (e.g., 400 round-trip miles). For a worst-case analysis of solid waste disposal trips, the maximum mileage of 400 round-trip miles was assumed.

Table 5-57
Alternative C: Delivery and Hauling Away Truck Types and Driving Distances

Substance	Travels as a:	Truck Type	Delivery Area	Peak Round-trip Mileage per Delivery	Delivery Status
Limestone	Aggregate	25-ton Heavy-duty Truck	Within SCAQMD	1	Increase
Merox Catalyst	Pre-mixed liquid	6,000 gallon tanker truck	Outside SCAQMD	500	Increase
NaOH (50% by weight)	Pre-mixed liquid	6,000 gallon tanker truck	Within SCAQMD	50	Increase
Solid Waste	Varies	25-ton Heavy-duty Truck	Within or Outside SCAQMD	1. 162 for in-District recycling or disposal; 2. 264 for out-of-District but in-state recycling; or, 3. 400 for out of state recycling (worst-case)	Increase
SOx Reducing Additives	Fine powder	25-ton Heavy-duty Truck	Outside SCAQMD	400	Increase
Sulfinol	Pre-mixed liquid	6,000 gallon tanker truck	Outside SCAQMD	500	Increase
Sulfur (Elemental)	Pre-mixed liquid	6,000 gallon tanker truck	Within SCAQMD	50	Increase
TG-10	Pre-mixed liquid	6,000 gallon tanker truck	Outside SCAQMD	400	Increase
MDEA	Pre-mixed liquid	6,000 gallon tanker truck	Within SCAQMD	50	No Change
DEA	Pre-mixed liquid	6,000 gallon tanker truck	Within SCAQMD	50	Decrease
MEA	Pre-mixed liquid	6,000 gallon tanker truck	Within SCAQMD	50	Decrease

A summary of the estimated truck trips of these substances per facility is provided in Tables 5-58 and 5-59 for Options 1 and 2 of Alternative C, respectively. The amount of peak daily truck trips associated with Alternative C is 27 for Option 1 and 24 for Option 2. Since neither option is expected to have an increase in heavy-duty transport truck traffic to and/or from any given facility by more than 350 truck round trips per day as shown in Tables 5-58 and 5-59, less than significant transportation impacts are expected from implementation either option of Alternative C. Further, taking into consideration the "worst-case" delivery and hauling transportation schedule, delivery and hauling trips associated with Alternative C are not expected to exceed, either individually or cumulatively, the current LOS of the areas surrounding the affected facilities during operations. Thus, the projected increase of traffic due to construction and operational activities is expected to be minimal and thus, the traffic impacts are expected to be less than significant for the proposed project.

		ALTERNATIVE C - OPTION 2: TOTAL	**24**	**6,726**	**225**	**93,968**

* A negative number means a reduction in usage or demand.

Though some of the facilities that will be affected by Alternative C are located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, actions that would be taken to comply with Alternative C, such as installing new air pollution control equipment, are not expected to significantly influence or alter air traffic patterns. Further, the size and type of air pollution control devices that would be installed would not be expected to affect navigable air space because they would not be substantially taller than other equipment at affected facilities. Thus, Alternative C would not result in a change in air traffic patterns, an increase in traffic levels or a change in location that results in substantial safety risks.

The siting of each existing affected facility is consistent with surrounding land uses and traffic/circulation in the surrounding areas of the affected facilities. Thus, Alternative C is not expected to substantially increase traffic hazards or create incompatible uses at or adjacent to the affected facilities. Aside from the temporary effects due to a slight increase in truck traffic when facilities undergo construction activities, Alternative C is not expected to alter the existing long-term circulation patterns. Alternative C is not expected to require a modification to circulation, thus, no long-term impacts on the traffic circulation system are expected to occur. Alternative C does not involve construction of any roadways, so there would be no increase in roadway design feature that could increase traffic hazards. Emergency access at each affected facility is not expected to be impacted by Alternative C. Further, each affected facility is expected to continue to maintain its existing emergency access gates.

Each affected facility will be expected to provide parking for the construction workers, as applicable, either on or within close proximity to each facility. No additional parking will be needed after completion of the construction phase because the work force at each facility is not expected to significantly increase as a result of Alternative C.

Lastly, construction and operation activities resulting from Alternative C are not expected to conflict with policies supporting alternative transportation since the proposed project does not involve or affect alternative transportation modes (e.g., bicycles or buses) because the construction and operation activities related to Alternative C will occur solely in existing industrial, commercial, and institutional areas. Based upon these considerations, significant transportation/traffic impacts are not expected from the implementation of Alternative C.

CONCLUSION

Table 5-60 summarizes all of the potential adverse environmental impacts from the proposed project and the alternatives.

Alternative A may not be a feasible alternative because it does not achieve any of the SOx emission reductions identified in the AQMP, which are necessary to demonstrate attainment with state and federal air quality standards. Even though Alternative A does not achieve the objectives of the proposed project and provides no benefit to air quality and public health, Alternative A would not be expected to generate any adverse environmental impacts. Thus, Alternative A is the environmentally superior alternative. However, if the "no project" alternative is determined to be the environmentally superior alternative, then the CEQA document shall identify an environmentally superior alternative among the other alternatives (CEQA Guidelines §15126.6 (e)(2)).

Alternative B, with a potential SOx emissions reduction of 1.50 tons per day, only partially achieves the SOx emission reductions identified in the AQMP, which are necessary to demonstrate attainment with state and federal air quality standards. When compared to the proposed project, Alternative B provides fewer benefits to air quality and public health. However, because Alternative B is limited to fewer source categories, fewer WGSs would be installed. Of the adverse environmental impacts that would be generated under Alternative B, the impacts would be less than the proposed project and less than significant, except for air quality construction emissions which are identical to the proposed project and are concluded to be significant. Lastly, Alternative B does not employ as much use of NaOH, a toxic. Thus,

S = Significant; NS = Not Significant
[2] A negative number means a reduction in usage or demand.

aside from the "no project" alternative, Alternative B is concluded to be the least toxic alternative. For these aforementioned reasons, Alternative B is concluded to be the environmentally superior alternative.

Alternative C, with a potential SOx emissions reduction of 5.48 tons per day, achieves slightly less potential SOx emission reductions than the proposed project. When compared to the proposed project, the GHG emissions projected for both options of Alternative C are significant, but less than the proposed project. Because Alternative C employs the same amount of NaOH for Option 1 and Option 2, respectively as the proposed project, it has equivalent toxic impacts when compared to the proposed project. Further, even though Alternative C would require less WGSs to be installed and would require less total water overall, both Option 1 and Option 2 of Alternative C are estimated to have equivalent demands of potable water when compared to Option 1 and Option 2 of the proposed project. Thus, Alternative C has equivalent potable water demand impacts as the proposed project. With regard to water quality, both Option 1 and Option 2 of Alternative C would generate less wastewater than Option 1 and Option 2 of the proposed project, respectively. Overall, Alternative C has less environmental impacts than the proposed project but it does not achieve the additional SOx reductions and health benefits expected from the proposed project.

All things considered, since the Basin is in non-attainment for PM2.5, for which SOx is a major precursor and since the 17 million residents of the South Coast Air Basin are experiencing the worst PM2.5 exposure in the nation, the proposed project achieves the largest amount of overall SOx reductions by relying on currently available SOx control technologies. It should be noted that SCAQMD staff has calculated that one ton of SOx reductions is equal to 15 tons of NOx reductions in progressing towards attainment of the PM2.5 standard. Although the proposed project also has the largest amount of adverse environmental impacts overall when compared to the alternatives, it achieves the maximum level of SOx reductions and corresponding health benefits. Each of the alternatives was crafted to show the various possibilities or permutations of how operators of SOx RECLAIM facilities could achieve actual SOx reductions, but ultimately, there is no way to predict what each facility operator will do. Thus, considering the PM2.5 exposure levels of the residents in the South Coast Air Basin and the need for expeditious improvement in PM2.5 air quality, the proposed project is preferred over Alternatives A, B, and C because it provides the most flexibility in the methods for reducing SOx emissions while maximizing the amount of potential SOx reductions and health benefits if the methods are implemented.

APPENDIX A (of the PEA)

PROPOSED AMENDED REGULATION XX:

Proposed Amended Rule 2002

In order to save space and avoid repetition, please refer to the latest version of proposed amended Rule 2002 located elsewhere in the Governing Board Package. The version of Proposed Amended Rule 2002 that was circulated with the Draft PEA and released on August 18, 2010 for a 45-day public review and comment period ending October 1, 2010 was dated August 17, 2010.

Original hard copies of the Draft PEA, which include the draft version of the proposed amended rule listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

Worksheet B-3
Phase II: Fugitive Dust

Fugitive PM10 Emissions Associated with foundation work for WGS Installation

1. GRADING ACTIVITIES (Backhoe)		
G = Fugitive PM10 Emission Rate (lbs/day) = 0.75 x T x 1.0 x $(S)^{1.5}$ x $(M)^{-1.4}$		*Source: AP-42, 10/98, Table 11.9-1 (PM10 Equation for Overburden Bulldozing)*
S = Silt Content	7.5 %	*Source: AP-42, 10/98, Table 11.9-3 (Correction Factors for Overburden Bulldozing)*
M = Moisture Content	2 %	*Source: AP-42, 10/98, Table 11.9-3 (Correction Factors for Overburden Bulldozing)*
T = max hours of operation/day	8 hr/day	
G = Fugitive PM10 =	**46.70 lbs/day**	

2. TRENCHING/STOCKPILE LOADING (Backhoe)		
LPM10 = Emission Factor per particle size (lbs/ton) = kPM10 x (0.0032) x $(U/5)^{1.3}$ x $(M/2)^{-1.4}$		*Source: AP-42, 01/95, p. 13.2.4-3 (Equation 1 for English Units)*
U = Mean Wind Speed	12 mile/hr	*Source: AP-42, 10/98, Table 11.9-5 (See Mine I)*
M = Material Moisture Content	2 %	*Source: AP-42, 10/98, Table 11.9-3 (Overburden Bulldozing)*
kPM10 = Particle Size Multiplier for PM10	0.35 dimensionless	*Source: AP-42, 01/95, p. 13.2.4-3*
G = Maximum Daily Weight of Material Moved	500 tons/day	Note: One backhoe can trench approximately 0.1 acre per day or 4,356 square feet per day, with a cut of 3 feet in depth, 13,068 cubic feet = 484 cubic yards and 1 cubic yard = 1 ton soil.
Tday, t = Truck Operating time, maximum	10 hr/day	
LPM10 = Emission Factor per particle size =	0.0035 lbs PM10/ton soil moved	
PPM10 = Emission Rate based on particle size = (LPMx G) =	**1.75 lbs PM10/day**	

3. STOCKPILE WIND EROSION		
Q = Wind Erosion Emission Rate based on particle size (lbs/day) = kPM10* 0.72 x U x Tc * (A x B /43,560 sq. ft/acre)		*Source: AP-42, 10/98, Table 11.9-1 (Emission Factor Equation for Active Storage Pile)*
A = Length of Stockpile	21 ft	
B = Width of Stockpile	21 ft	
U = Mean Wind Speed	12 mile/hr	*Source: AP-42, 10/98, Table 11.9-5 (General Characteristics of Surface Coal Mines - Mine I)*
kPM10 = Particle Size Multiplier for PM10	0.5 dimensionless	*Source: AP-42, 01/95, p. 13.2.5-3 (PM10 Aerodynamic Particle Size Multiplier (k) for Equation 2)*
Tc = Time Piles Remain Uncovered	24 hr/day	Note: This calculation assumes that the piles remain uncovered for 24 hours/day.
QPM10 =	**1.05 lbs PM10/day**	

4. TRUCK FILLING/DUMPING		
TF = Fugitive PM10 Emissions From Truck Filling = G (ton/day) x TF, PM10 (lb/ton)		
TD = Fugitive PM10 Emissions From Truck Dumping = G (ton/day) x TD, PM10 (lb/ton)		
TFPM10 = Emission Factor for Truck Filling =	0.0221 lb/ton of material moved	
TDPM10 = Emission Factor for Truck Dumping =	0.0091 lb/ton of material moved	
G = Maximum Daily Weight of Material Trucked Away	500 ton/day	
TF =	**11.03 lbs PM10/day**	
TD =	**4.64 lbs PM10/day**	

FUGITIVE PM10 EMISSIONS SUMMARY

		33	trucks/day	Daily no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		127,768	round trip miles/year	Annual truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		362	trucks/year	Annual no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				

Note 1: Instantaneous Electricity Equation: 197,611 kW-hr/day x 1 work day/24 hr x 1 MW/1000 kW = 8.2 MW

Note 2: This calculation takes into account the electricity needed to make 9.9 tons per day of NaOH to satisfy demand (22,444 kWh/day).

*See Hydrology/Water Quality Analysis

*See Hydrology/Water Quality Analysis

Key:
Cooling water already accounted for in both water demand and energy demand.
NaOH is 50% by weight, usually delivered by tanker truck in an aqueous solution due to high concentration

1 scf = 1020 BTU for natural gas

1 MW = 1000 KW
1 tcf (trillion cubic feet) = 1000 bcf (billion cubic feet) = 1,000,000 MMcf (million cubic feet)

1 metric ton = 2205 lbs

Phase III: Operations - On-Road Vehicles and Fuel Use

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO2/MMscf fuel burned
0.64 lb N20/MMscf fuel burned
2.3 lb CH4/MMscf fuel burned
1,110 lb CO2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water[1]
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation[2]
640 lb CO2/MWh for electricity use due to water conveyance
0.0067 lb CH4/MWh for electricity use due to water conveyance
0.0037 lb N2O/MWh for electricity use due to water conveyance

0	trucks/day	No. of Trucks Hauling Away Solid Waste
8000	round trip miles/year	Annual Truck Miles
20	trucks/year	Annual Trucks

Coke Calciner 1 facility - 1 WGS		
Usage Rates		
0	MMbtu/day	Natural Gas
17,711	kWh/day	Electricity
40,896	gal/day	Water
16,992	gal/day	Wastewater
0	Mmbtu/day	Cooling Water
0	scf/day	Compressed Air
0.44	tons/day	Solid Waste Disposal
3	tons/day	NaOH (50%)
1,200	sf	plot space needed
450	round trip miles/day	truck miles driven
2	trucks/day	no. of trucks
4,400	round trip miles/year	truck miles driven
39	trucks/year	no. of trucks

Sulfuric Acid Plant - part 1 1 facility - 1 WGS		
Usage Rates		
0	MMbtu/day	Natural Gas
9,659	kWh/day	Electricity
19,589	gal/day	Water
10,800	gal/day	Wastewater
0	Mmbtu/day	Cooling Water
0	scf/day	Compressed Air
0	tons/day	Solid Waste Disposal
1	tons/day	NaOH (50%)
500	sf	plot space needed
50	round trip miles/day	truck miles driven
1	trucks/day	no. of trucks
650	round trip miles/year	truck miles driven
13	trucks/year	no. of trucks

*any increase in SOx Reducing Catalyst is a direct reduction in FCCU regenerator catalyst

Notes:

Facility A already uses SOx reducing additives, but not sure how much

Facility B already uses 800 lb/day of SOx reducing additives

Facility C no longer needs to use SOx reducing additives
Facility D does not currently use SOx reducing additives
Facility E has been testing with SOx reducing additives
Facility F already uses SOx reducing additives, but not sure how much

Brands of SOx reducing additives:
Intercat Super SOx-Getter
Grace Davison Super DeSOx

Most refineries are already using Grace Davison's base catalyst and sox reducing catalyst

Worksheet B-7
Proposed Project - Option 2: Grand Totals

Sulfuric Acid Plant - part 2		
1 facility - existing system upgrade

Worksheet B-7
Proposed Project - Option 2: Grand Totals

GRAND TOTALS (For Operation)									
Usage Rates					Notes	Net Effect of Project		Percentage Change	Significant?
-4.11	MMbtu/day	-4029.01	scf/day	Natural Gas	Significance Threshold: 1% of supply (9330 MMcf of Natural Gas /day)	-0.0040	MMscf/day	-0.00004%	NO
100,721	kWh/day	100.72	MWh/day	Electricity	Significance Threshold: 1% of supply (8362 MW - instantaneous electricity)	4.20	MW (instantaneous)	0.05%	NO
642,271	gal/day	0.64	MMgal/day	Water	Significance Threshold: 5,000,000 gal/day water	642,271	gal/day	12.85%	NO
158,203	gal/day	0.16	MMgal/day	Wastewater	Significance Threshold: 25% increase above permitted wastewater limits	158,203	gal/day	<25%*	NO
		1,761	MMbtu/day	Cooling Water	This data already included in energy calculations.				
		21,096	scf/day	Compressed Air	This data already included in energy calculations.				
		7.56	tons/day	Solid Waste Disposal	Solid Waste Disposal, Air Quality off-site transportation emissions, & Energy (fuel usage)				
		952.15	pounds/day	Sulfur sales*	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		16.44	pounds/day	Merox Catalyst	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		2500.00	pounds/day	SOx Reducing Catalyst	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		10.96	gal/day	TG-10 amine additive	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		0.86	tons/day	Soda Ash (Na_2CO_3)	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		1.10	pounds/day	ESX Catalyst	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		8.79	tons/day	NaOH (50% by weight)	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		2.98	tons/day	Limestone - $CaCO_3$	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		2173	gal/day	sulfinol	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		-1373.95	gal/day	MEA	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		-789.041	gal/day	DEA	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		40,976	sf	Plot Space Needed	Air Quality: grading/site-preparation construction emissions				
		16,076	round trip miles/day	Daily truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		30	trucks/day	Daily no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		108,318	round trip miles/year	Annual truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		274	trucks/year	Annual no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				

Note 1: Instantaneous Electricity Equation: 100,721 kW-hr/day x 1 work day/24 hr x 1 MW/1000 kW = 4.2 MW

Note 2. This calculation takes into account the electricity needed to make 8.79 tons per day of NaOH to satisfy demand (19,940 kWh/day).

*See Hydrology/Water Quality Analysis

*See Hydrology/Water Quality Analysis

Key:
Cooling water already accounted for in both water demand and energy demand.
NaOH is 50% by weight; usually delivered by tanker truck in an aqueous solution due to high concentration
1 scf = 1020 BTU for natural gas
1 MW = 1000 KW
1 tcf (trillion cubic feet) = 1000 bcf (billion cubic feet) = 1,000,000 MMcf (million cubic feet)
1 metric ton = 2205 lbs

Phase III: Operations - On-Road Vehicles and Fuel Use

Phase III: Operation		Annual Round-trip Distance	Mileage Rate	2012 Mobile Source Emission Factors

125285	gal/day	0.13	MMgal/day	Water	Significance Threshold: 5,000,000 gal/day water	125,285	gal/day	2.51%	NO
40669	gal/day	0.04	MMgal/day	Wastewater	Significance Threshold: 25% increase above permitted wastewater limits	40,669	gal/day	<25%*	NO
		0	MMbtu/day	Cooling Water	This data already included in energy calculations.				
		110	scf/day	Compressed Air	This data already included in energy calculations.				
		0.49	tons/day	Solid Waste Disposal	Solid Waste Disposal, Air Quality off-site transportation emissions, & Energy (fuel usage)				
		5.45	tons/day	NaOH (50% by weight)	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		2,340	sf	Plot Space Needed	Air Quality: grading/site-preparation construction emissions				
		683	round trip miles/day	Daily truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		5	trucks/day	Daily no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		5,583	round trip miles/year	Annual truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		61	trucks/year	Annual no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				
99360	gal/day	0.10	MMgal/day	No access to recycled water					
25925	gal/day	0.03	MMgal/day	future access to recycled water					
29869	gal/day	0.03	MMgal/day	Wastewater (with no access to recycled water)					
10800	gal/day	0.01	MMgal/day	Wastewater (with future access to recycled water)					

Note 1: Instantaneous Electricity Equation: 33,064 kW-hr/day x 1 work day/24 hr x 1 MW/1000 kW = 1.4 MW

Note 2: This calculation takes into account the electricity needed to make 5.45 tons per day of NaOH to satisfy demand (12,361 kWh/day)

*See Hydrology/Water Quality Analysis

*See Hydrology/Water Quality Analysis

Key:
Cooling water already accounted for in both water demand and energy demand.
NaOH is 50% by weight usually delivered by tanker truck in an aqueous solution due to high concentration.
1 scf = 1020 BTU for natural gas
1 MW = 1000 kW
1 tcf (trillion cubic feet) = 1000 bcf (billion cubic feet) = 1,000,000 MMcf (million cubic feet)
1 metric ton = 2205 lbs

Phase III: Operations - On-Road Vehicles and Fuel Use

Phase III: Operation		Annual Round-trip Distance	Mileage Rate	2012 Mobile Source Emission Factors							
On-Road Equipment Type	Fuel	(miles/year)	(miles/gallon)	VOC (lb/mile)	CO (lb/mile)	NOx (lb/mile)	SOx (lb/mile)	PM10 (lb/mile)	PM2.5 (lb/mile)	CO2 (lb/mile)	CH4 (lb/mile)
Offsite (Heavy-Heavy Duty Truck)	diesel	5,583	4.89	0.0025	0.0102	0.0309	0.00004	0.0015	0.0013	4.2159	0.0001

*Assumes 260 days/year

Incremental Increase in Offsite Combustion Emissions from Operation Vehicles	VOC (lb/day)	CO (lb/day)	NOx (lb/day)	SOx (lb/day)	PM10 (lb/day)	PM2.5 (lb/day)	CO2 (lb/year)	CH4 (lb/year)	CO2e (lb/year)	CO2e (MT*/year)
Offsite (Heavy-Heavy Duty Truck)	0.05	0.22	0.68	0.001	0.03	0.03	23,536	0.65	23,550	11

		6,526	round trip miles/day	Daily truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		27	trucks/day	Daily no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		113,418	round trip miles/year	Annual truck miles driven	Air Quality: off-site transportation emissions & Energy (fuel usage)				
		313	trucks/year	Annual no. of trucks	Air Quality: off-site transportation emissions & Energy (fuel usage)				

Note 1: Instantaneous Electricity Equation:
182,218 kW-hr/day x 1 work day/24 hr x 1 MW/1000 kW = 7.6 MW

*See Hydrology/Water Quality Analysis

*See Hydrology/Water Quality Analysis

Note 2: This calculation takes into account the electricity needed to make 13.24 tons per day of NaOH to satisfy demand (30,023 kWh/day).

Key:
Cooling water already accounted for in both water demand and energy demand.
NaOH is 50% by weight, usually delivered by tanker truck in an aqueous solution due to high concentration.
1 scf = 1020 BTU for natural gas
1 MW = 1000 KW
1 tcf (trillion cubic feet) = 1000 bcf (billion cubic feet) = 1,000,000 MMcf (million cubic feet)
1 metric ton = 2205 lbs

Phase III: Operations - On-Road Vehicles and Fuel Use

*any increase in SOx Reducing Catalyst is a direct reduction in FCCU regenerator catalyst

Notes:

Facility A already uses SOx reducing additives, but not sure how much

Facility B already uses 800 lb/day of SOx reducing additives

Facility C no longer needs to use SOx reducing additives

Facility D does not currently use SOx reducing additives
Facility E has been testing with SOx reducing additives
Facility F already uses SOx reducing additives, but not sure how much

Brands of SOx reducing additives:

Intercat Super SOx-Getter

Grace Davison Super DeSOx

Most refineries are using Grace Davison's base catalyst and sox reducing catalyst.

[1]Assumes catalyst deliveries are made by a 25 ton capacity truck. It will take an extra 19 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.
456.25 tons/yr catalyst x 1 truck/25 tons = 18.25 trucks/year to deliver extra catalyst

[2]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 78 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
1938.15 tons/yr solid waste x 1 truck/25 tons = 78 trucks/year to haul extra solid waste away for recycling

2.00	Daily trucks	Total No. of Trucks			
2585.00	Annual round trip miles	Annual Truck Miles			
64	Annual trucks	Annual Trucks			

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take 37 extra trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
454 tons/yr solid waste x 2 units X 1 truck/25 tons = 36.32 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a Class III landfill for disposal which is 71.06 miles (one-way) away.

[2]Assumes Hauling Limestone from quarry to unit in a 25 ton capacity truck. It will take 27 extra truck trips to haul one year's worth of limestone, but the peak would be one truck per day.
336 tons/yr limestone x 2 units x 1 truck/25 tons = 26.88 trucks/year to haul limestone from the quarry to the equipment
The distance between the quarry and the facility is less than one mile (one-way) away because the cement plant is located on its own quarry.

Phase III: Operations - On-Road Vehicles and Fuel Use

Phase III: Operation On-Road Equipment Type	Fuel	Annual Round-trip Distance (miles/year)	Mileage Rate (miles/ gallon)	2012 Mobile Source Emission Factors VOC (lb/mile)	CO (lb/mile)	NOx (lb/mile)	SOx (lb/mile)	PM10 (lb/mile)	PM2.5 (lb/mile)	CO2 (lb/mile)	CH4 (lb/mile)

Plot Space Needed	320	sf	320	sf	640	sf	**Plot Space Needed**		
1 Truck Hauling Away Solid Waste[1]	132.78	round trip miles	132.78	round trip miles	132.78	Daily round trip miles	**1 Truck Hauling Away Solid Waste**[1]		
1 Truck Delivering NaOH[2]	200	round trip miles	50.00	round trip miles	50.00	Daily round trip miles	**1 Truck Delivering NaOH**[2]		
No. of Trucks Hauling Away Solid Waste	1	trucks	1	truck	1.00	daily trucks	**No. of Trucks Hauling Away Solid Waste**		
No. of Trucks Delivering NaOl	4	trucks	1	truck	1	daily trucks	**No. of Trucks Delivering NaOH**		
					182.78	Daily round trip miles	**Total Daily Truck Miles**		
					2.00	Daily trucks	**Total No. of Trucks**		
					532.78	Annual round trip miles	**Annual Truck Miles**		
					9	Annual trucks	**Annual Trucks**		

Note: This calculation takes into account the electricity needed to make 0.79 ton per day of NaOH to satisfy demand (1,791 kWh/day).

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of solid waste, but the peak would be one truck per day.
10 tons/yr solid waste x 2 units x 1 truck/25 tons = 0.8 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a Class III landfill for disposal which is 66.4 miles (one-way) away.

[2]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 8 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
144 tons/yr NaOH x 2 units x 2,000 lbs/ ton = 576,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 45,106 gal/year x 1 truck/6,000 gallons = 7.5 trucks/year

This facility is not tied into Central Basin Municipal Water District's recycled water pipeline. Access to the pipeline is approx. 800 feet away from the facility.

temporary construction activities[3]	4657.40	MT/year	Construction GHGs in CO2e				155
operational truck trips	1.02	MT/year	Operation GHGs in CO2e				1
						TOTAL CO2e	1,289

Note: This facility does not have current access or future access to recycled water.

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO2/MMscf fuel burned
0.64 lb N2O/MMscf fuel burned
2.3 lb CH4/MMscf fuel burned
1,110 lb CO2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation
640 lb CO2/MWh for electricity use due to water conveyance
0.0067 lb CH4/MWh for electricity use due to water conveyance
0.0037 lb N2O/MWh for electricity use due to water conveyance

[3]GHGs from temporary construction activities are amortized over 30 years.

Facility H - Coke Calciner
Belco wet gas scrubber

Utility/Infrastructure	Annual Usage		Daily Usage		Daily Usage		
Natural Gas	0	MMbtu	0.00	MMbtu	0.00	scf	
Electricity	3,679,200	kWh	17710.86	kWh	17.71	MWh	Note: This calculation takes into account the electricity needed to make 3.37 tons per day of NaOH to satisfy demand (7,631 kWh/day).
Water	14.93	MMgal	40896.00	gal	0.04	Mmgal	
Wastewater	6.2	MMgal	16992.00	gal	0.02	Mmgal	
Cooling Water	0	MMbtu	0.00	MMbtu			
Compressed Air	0	1000 scf	0.00	scf			
Solid Waste Disposal	160	tons	0.44	tons			
NaOH (50%)	1,228	tons	3.37	tons	22	gal/hr	280.434 lb/hr
Plot Space Needed	1200	sf			density = 12.747 lb/gal for NaOH at 50%		
1 Truck Hauling Away Solid Waste[1]	2800	round trip miles	400.00	round trip miles			
1 Truck Delivering NaOH[2]	1,600	round trip miles	50.00	round trip miles			
No. of Trucks Hauling Away Solid Waste	7	trucks	1	truck			
No. of Trucks Delivering NaOH	32	trucks	1	truck			
Total Truck Miles	4400.00	round trip miles	450.00	round trip miles			
Total No. of Trucks	39.00	trucks	2.00	trucks			

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 7 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
160 tons/yr solid waste x 1 truck/25 tons = 6.4 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant for recycling which is 67.7 miles (one-way) away. However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement l

[2]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 32 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
1,228 tons/yr NaOH x 2,000 lbs/ ton = 854,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 192,326 gal/year x 1 truck/6,000 gallons = 32 trucks/year

						TOTAL CO2e	3,772

Note: The mitigation calculations assume that 100% of the total water demand for FGT can potentially be supplied by recycled water for Facilities A, C, D, E & F.
Facilities A & D already have access to recycled water and Facility G already has access to non-potable groundwater.
Facilities C, E & F may have new future access to recycled water.

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO2/MMscf fuel burned
0 64 lb N2O/MMscf fuel burned
2 3 lb CH4/MMscf fuel burned
1,110 lb CO2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water[1]
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation[2]
640 lb CO2/MWh for electricity use due to water conveyance
0 0067 lb CH4/MWh for electricity use due to water conveyance
0 0037 lb N2O/MWh for electricity use due to water conveyance

Module 2: SRU/TGTU Systems M13: EmeraChem ESx Gas Treating	Facility A		
Utility/Infrastructure	Annual Usage		Daily Usage
Natural Gas	11,000	MMbtu	30.14 MMbtu
Electricity	1,085,000	kWh	2972.60 kWh
Water	0	MMgal	0.00 gal
Wastewater	0	MMgal	0.00 gal
Cooling Water	40	MMbtu	0.11 MMbtu
Compressed Air	770	1000 scf	2109.59 scf
Solid Waste Disposal	0	tons	0.00 tons
Esx Catalyst	400	pounds	1.10 pounds
Sulfur sales[4]	23.66	long tons	145.20 pounds
Plot Space Needed	2500	sf	
		round trip	round trip
1 Truck Hauling Sulfur Away[4]	100	miles	50.00 miles
		round trip	round trip
1 Truck Delivering ESX Catalyst[5]	400	miles	400.00 miles
No. of Trucks Hauling Sulfur Away	2	trucks	1 truck
No. of Trucks Delivering ESX Catalyst	1	trucks	1 truck

Facility A already accesses recycled water and will have increased future access to recycled water.

[1]Assumes that the existing DEA amine storage tank can be used for Sulfinol storage.

[2]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 12 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.

280 tons/yr solid waste x 1 truck/25 tons = 11.2 trucks/year to haul extra solid waste away for recycling

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 8 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.

294 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 46,045 gal/year x 1 truck/6,000 gallons = 7.67 trucks/year

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take an extra 2 trucks to haul away one year's worth of sulfur, but the peak would be one truck per day.
23.66 long tons/yr Sulfur x 2,240 lbs/long ton = 52,998 lbs/yr x 1 ton/2000 lbs = 26.5 tons/yr x 1 truck/25 tons = 1.06 trucks/year to haul extra sulfur away to a buyer

[5] It will take one truck to deliver one year's worth of ESX Catalyst, but the peak would be one truck per day.

Facility A estimated that a wet gas scrubber would generate 40 million gals per year wastewater = 109,589 gals per day.
Facility A has two distinct wastewater systems. System One is the un-segregated system, which handles water from cooling towers, boiler blowdowns, and stormwater.

This wastewater receives primary treatment, the maximum capacity for this system is 5000 gpm; the facility is currently running at about 3000 gpm.

System Two is the segregated system, which handles process water. This wastewater receives primary and secondary (biological) treatment. The maximum capacity for this system is 2000 gpm; the facility is currently running at about 1800 gpm.
Facility A has some wastewater storage capacity to handle surges due to storms and upsets.

No. of Trucks Delivering NaOH	12	trucks	1	truck

Facility B will have increased access to recycled water.

Module 3A: SRU/TGTU Systems
M17: Tail Gas NWGS Tri-Mer Cloud Chamber

Utility/Infrastructure	Facility B Annual Usage for 2 units		Facility B Daily Usage for 2 units	
Natural Gas	0	MMbtu	0.00	MMbtu
Electricity	4,395,600	kWh	12042.74	kWh
Water	51.1	MMgal	140000.00	gal
Wastewater	10.2	MMgal	27945.21	gal
Cooling Water	409,880	MMbtu	1122.96	MMbtu
Compressed Air	100	1000 scf	273.97	scf
Solid Waste Disposal	500	tons	1.37	tons
Soda Ash	190	tons	0.52	tons
Plot Space needed	7906	sf		
1 Truck Hauling Away Solid Waste[3]	8000	round trip miles	400.00	round trip miles
1 Truck Delivering Soda Ash[4]	400	round trip miles	50.00	round trip miles
No. of Trucks Hauling Away Solid Waste	20	trucks	1	truck
No. of Trucks Delivering Soda Ash	8	trucks	1	truck

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 16 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
400 tons/yr solid waste x 1 truck/25 tons = 16 trucks/year to haul extra solid waste away for recycling
This facility either sends its solid waste to a Class III landfill for disposal which is 80.64 miles (one-way) away or to a cement plant for recycling which is 67.48 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[2]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 12 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
427 tons/yr NaOH x 2,000 lbs/ ton = 854,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 66,875 gal/year x 1 truck/6,000 gallons = 11.1 trucks/year

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 20 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
500 tons/yr solid waste x 1 truck/25 tons = 20 trucks/year to haul extra solid waste away for recycling
This facility either sends its solid waste to a Class III landfill for disposal which is 80.64 miles (one-way) away or to a cement plant for recycling which is 67.48 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[4]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 8 trucks to deliver one year's worth of soda ash.
190 tons/yr soda ash x 1 truck/25 tons = 7.6 trucks/year to deliver soda ash

For Facility B, AEC recommends Measure M1 [from Module 3A] for the FCCU, Measure M17 [from Module 3A] for the SRU/TGTU, and Measure M20 [from Module 2] for fuel gas treatment.
Can buy recycled water from California Water Service Company.

Facility B already accesses recycled water and will have increased future access to recycled water.

Plot Space Needed	5930	sf		
1 Truck Hauling Away Solid Waste[5]	5200	round trip miles	400.00	round trip miles
1 Truck Delivering Soda Ash[6]	250	round trip miles	50.00	round trip miles
No. of Trucks Hauling Away Solid Waste	13	trucks	1	truck
No. of Trucks Delivering Soda Ash	5	trucks	1	truck

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 5 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
110 tons/yr solid waste x 1 truck/25 tons = 4.46 trucks/year to haul extra solid waste away for recycling

[2]It will take one truck to deliver one year's worth of Merox catalyst; the peak would be one truck per day.
Merox is delivered by truck from Chicago. The distance from the California/Nevada border to this facility is approximately 250 miles, one-way.

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 5 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
160 tons/yr NaOH x 2,000 lbs/ ton = 320,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,059 gal/year x 1 truck/6,000 gallons = 4.2 trucks/year

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of sulfur; the peak would be one truck per day.
11 long tons/yr Sulfur x 2,240 lbs/long ton = 24,640 lbs/yr x 1 ton/2000 lbs = 12.32 tons/yr x 1 truck/25 tons = 0.49 trucks/year to haul extra sulfur away to a buyer

[5]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 13 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
320 tons/yr solid waste x 1 truck/25 tons = 12.8 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant for recycling which is 68.42 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[6]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 5 trucks to deliver one year's worth of soda ash.
123 tons/yr soda ash x 1 truck/25 tons = 4.92 trucks/year to deliver soda ash

For Facility D, AEC recommends Measure M1 [from Module 3A] for the FCCU, Measure M17 [from Module 3A] for the SRU/TGTU, and Measure M21A [from Module 2] for the fuel gas treatment system.
Facility D can buy recycled water from California Water Service Company.

Plot Space Needed	2500	sf		

Excluded - not cost effective

[1]Assumes that the existing DEA amine storage tank can be used for Sulfinol storage.

[2]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take an extra 3 trucks to haul away one year's worth of sulfur, but the peak would be one truck per day.

56.56 long tons/yr Sulfur x 2,240 lbs/long ton = 126,695 lbs/yr = 63.35 tons/yr x 1 truck/25 tons = 2.53 trucks/year to haul extra sulfur away to a buyer

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 7 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.

160 tons/yr solid waste x 1 truck/25 tons = 6.4 trucks/year to haul extra solid waste away for recycling

This facility sends its solid waste to a cement plant for recycling which is 66.47 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[4]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 5 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
164 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,685 gal/year x 1 truck/6,000 gallons = 4.28 trucks/year

Sulfur sales*	20.88	long tons	128.14	pounds
Plot Space needed	2500	sf		

Excluded - Facility F already meets the 5 ppm SOx level

[1]Assumes that one 5,000 gallon capacity storage tank will be installed for TG-10 storage. It will take 1 truck to deliver one year's worth of TG-10 solution, but the peak would be one truck per day.
4,000 gal/year x 1 truck/6,000 gallons = 0.67 trucks/year

[2]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of sulfur; the peak would be one truck per day.

10.35 long tons/yr Sulfur x 2,240 lbs/long ton = 23,184 lbs/yr x 1 ton/2000 lbs = 11.59 tons/yr x 1 truck/25 tons = 0.46 trucks/year to haul extra sulfur away to a buyer

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 28 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
690 tons/yr solid waste x 1 truck/25 tons = 27.6 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant for recycling which is 67.48 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[4]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 20 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
738 tons/yr NaOH x 2,000 lbs/ ton = 1,476,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 115,583 gal/year x 1 truck/6,000 gallons = 19.2 trucks/year

Phase III: Operations - On-Road Vehicles and Fuel Use

Daily round 50.00 trip miles		1 Truck Hauling Sulfur Away[4]
1.00 daily trucks		No. of Trucks Hauling Away Solid Waste
1.00 daily trucks		No. of Trucks Delivering Merox Catalyst
1.00 daily trucks		No. of Trucks Delivering NaOH
1.00 daily trucks		No. of Trucks Hauling Sulfur Away
Daily round 1000.00 trip miles		Total Daily Truck Miles
4.00 Daily trucks		Total No. of Trucks
Annual round trip 14,000 miles		Annual Truck Miles
Annual 61 trucks		Annual Trucks

Note: This calculation takes into account the electricity needed to make 2.9 tons per day of NaOH to satisfy demand (6,535 kWh/day).

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 30 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
740 tons/yr solid waste x 1 truck/25 tons = 29.6 trucks/year to haul extra solid waste away for recycling

[2]It will take one truck to deliver one year's worth of Merox catalyst; the peak would be one truck per day.
Merox is delivered by truck from Chicago. The distance from the California border to this facility is approximately 250 miles, one-way.

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 28 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
1,060 tons/yr NaOH x 2,000 lbs/ ton = 2,120,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 166,014 gal/year x 1 truck/6,000 gallons = 27.7 trucks/year

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 2 extra trucks to haul away one year's worth of sulfur; the peak would be one truck per day.
47 long tons/yr Sulfur x 2,240 lbs/long ton = 105,280 lbs/yr x 1 ton/2000 lbs = 52.64 tons/yr x 1 truck/25 tons = 2.1 trucks/year to haul extra sulfur away to a buyer

For Facility G, consultant recommends M21B for the fuel gas treatment systems.
Measures for the SRU/TGTU are more costly, with the best opportunity at Facility G being M17 [Module 3A].
For heaters, boilers, and furnaces, M30 [Module 3A] is the best opportunity for Facility G.
Facility G will not have future access to recycled water, but currently uses non-potable well water to supply the facility.

Module 3A: SRU/TGTU Systems
M17: Tail Gas NWGS
Tri-Mer Cloud

Disposal Facilities Used by Facility B

Facility Name	Facility Type	Facility Class	Remaining Capacity (yds^3)	Address	Mileage	Permitted Capacity (yds^3)
Waste Management - Palmdale (Los Angeles County): Antelope Valley Public Landfill	Solid waste landfill Large volume waste transfer facility	Class III	2, 980,000	1200 West City Ranch Road, Palmdale CA 93551	80.64 from Facility B 66.39 from Facility I 71.06 from Facility K	6,480,000
Waste Management - Azusa (Los Angeles County): Azusa Land Reclamation Co. Landfill	Inert waste disposal site Major waste tire facility Asbestos Containing Materials disposal site Contaminated soil facility Solid waste disposal site	Class III	34,100,000	1211 West Gladstone Street, Azusa, CA 91702	34.34 from Facility B 23.65 from Facility I 38.77 from Facility K	66,670,000

Source:
www.cwmb.c

Facility A sends its solid waste to a cement plant for recycling which is 71.9 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).
Facility A's catalyst fines are collected by a pneumatic tanker truck (USA Transport) and are transported to California Portland Cement, Colton, CA for recycling into cement.
In 2008 the facility shipped 408.61 tons. Analytical data has shown these catalyst fines to be non-hazardous.

Facility D sends its solid waste to a cement plant for recycling which is 68.42 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

Facility G sends its solid waste to a cement plant for recycling which is 66 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

PROPOSED PROJECT - OPTION 2: FCCUs USING SOx REDUCING ADDITIVES ONLY

FCCUs 6 Refineries Using SOx Reducing Additives to meet 5 ppm SOx limit Usage Rates		
0	Mmbtu/day	Natural Gas

http://www.agmd.gov/ceqa/handbook/onroad/onroad.html/onroadEFHHDT07_26.xls

Notes:
Facility A already uses SOx reducing additives, I
Facility B already uses 800 lb/day of SOx reducing additives
Facility C no longer needs to use SOx reducing additives
Facility D does not currently use SOx reducing additives
Facility E has been testing with SOx reducing additives
Facility F already uses SOx reducing additives, but not sure how much

[1]Assumes catalyst deliveries are made by a 25 ton capacity truck. It will take an extra 20 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.
[2]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take 0 extra trucks to haul away one year's worth of solid waste.

Brands of SOx reducing additives: Intercat Super SOx-Getter Grace Davison Super DeSOx Most refineries are using Grace Davison's base catalyst and SOx reducing catalyst.

Phase III: Operations - GHG Emissions - Unmitigated

GHG Activity	Amount	Units	GHG Emissions Source	CO2 (MT/yr)	N2O (MT/yr)	CH4 (MT/yr)	Total CO2e (MT/yr)

Module 2:
SRU/TGTU Systems
M13: EmeraChem ESx Gas Treating

Facility A				
Utility/Infrastructure	Annual Usage		Daily Usage	
Natural Gas	11,000	MMbtu	30.14	MMbtu
Electricity	1,085,000	kWh	2972.60	kWh
Water	0	MMgal	0.00	gal
Wastewater	0	MMgal	0.00	gal
Cooling Water	40	MMbtu	0.11	MMbtu
Compressed Air	770	1000 scf	2109.59	scf
Solid Waste Disposal	0	tons	0.00	tons
ESX Catalyst	400	pounds	1.10	pounds
Sulfur sales*	23.66	long tons	145.20	pounds
Plot Space Needed	2500	sf		
				round trip
1 Truck Hauling Sulfur Away[4]	100	round trip miles	50.00	miles
				round trip
1 Truck Delivering ESX Catalyst[5]	400	round trip miles	400.00	miles
No. of Trucks Hauling Sulfur Away	2	trucks	1	trucks
No. of Trucks Delivering ESX Catalyst	1	trucks	1	trucks

Facility A already accesses recycled water and will have increased future access to recycled water.

[1]Assumes that the existing DEA amine storage tank can be used for Sulfinol storage.

[2]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take 0 extra trucks to haul away one year's worth of solid waste.

[3]Assumes that one 25-ton truck will deliver catalyst. It will take 4 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.

One bulk catalyst truck can transport 25 tons.

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take an extra 2 trucks to haul away one year's worth of sulfur, but the peak would be one truck per day.
23.66 long tons/yr Sulfur x 2,240 lbs/long ton = 52,998 lbs/yr x 1 ton/2000 lbs = 26.5 tons/yr x 1 truck/25 tons = 1.06 trucks/year to haul extra sulfur away to a buyer

[5] It will take one truck to deliver one year's worth of ESX Catalyst, but the peak would be one truck per day.

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take 0 extra trucks to haul away one year's worth of solid waste.

[2]Assumes that one 25-ton truck will deliver catalyst. It will take 4 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.

One bulk catalyst truck can transport 25 tons.

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 20 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
500 tons/yr solid waste x 1 truck/25 tons = 20 trucks/year to haul extra solid waste away for recycling
This facility either sends its solid waste to a Class III landfill for disposal which is 80.64 miles (one-way) away or to a cement plant for recycling which is 67.48 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[4]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 8 trucks to deliver one year's worth of soda ash.
190 tons/yr soda ash x 1 truck/25 tons = 7.6 trucks/year to deliver soda ash

Solid Waste Disposal	320	tons	0.88 tons
Soda Ash	123	tons	0.34 tons
Plot Space Needed	5930	sf	
1 Truck Hauling Away Solid Waste[5]	5200	round trip miles	round trip 400.00 miles
1 Truck Delivering Soda Ash[6]	250	round trip miles	round trip 50.00 miles
No. of Trucks Hauling Away Solid Waste	13	trucks	1 truck
No. of Trucks Delivering Soda Ash	5	trucks	1 truck

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 5 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.

110 tons/yr solid waste x 1 truck/25 tons = 4.48 trucks/year to haul extra solid waste away for recycling

[2]It will take one truck to deliver one year's worth of Merox catalyst; the peak would be one truck per day.
Merox is delivered by truck from Chicago. The distance from the California/Nevada border to this facility is approximately 250 miles, one-way.

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 5 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.

160 tons/yr NaOH x 2,000 lbs/ ton = 320,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,059 gal/year x 1 truck/6,000 gallons = 4.2 trucks/year

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of sulfur; the peak would be one truck per day.
11 long tons/yr Sulfur x 2,240 lbs/long ton = 24,640 lbs/yr x 1 ton/2000 lbs = 12.32 tons/yr x 1 truck/25 tons = 0.49 trucks/year to haul extra sulfur away to a buyer

[5]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 13 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
320 tons/yr solid waste x 1 truck/25 tons = 12.8 trucks/year to haul extra solid waste away for recycling
This facility sends its solid waste to a cement plant for recycling which is 88.42 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[6]Assumes delivery of soda ash arrives in a 25 ton capacity truck. It will take an extra 5 trucks to deliver one year's worth of soda ash.
123 tons/yr soda ash x 1 truck/25 tons = 4.92 trucks/year to deliver soda ash

[7]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take 0 extra trucks to haul away one year's worth of solid waste.

[8]Assumes that one 25-ton truck will deliver catalyst. It will take 4 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.
One bulk catalyst truck can transport 25 tons.

Note: The mitigation calculations assume that 100% of the total water demand for this facility can potentially be supplied by recycled water.

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO2/MMscf fuel burned
0.64 lb N20/MMscf fuel burned
2.3 lb CH4/MMscf fuel burned
1,110 lb CO2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation
640 lb CO2/MWh for electricity use due to water conveyance
0.0067 lb CH4/MWh for electricity use due to water conveyance
0.0037 lb N2O/MWh for electricity use due to water conveyance

1 Truck Hauling Sulfur Away[2]	50	round trip miles	50.00	round trip miles
No. of Trucks Delivering TG-10	1	trucks	1	truck
No. of Trucks Hauling Sulfur Away	1	trucks	1	truck

SOx Reducing Additive for FCCU	Facility F			
Utility/Infrastructure	Annual Usage		Daily Usage	
Natural Gas	0	MMbtu	0.00	MMbtu
Electricity	0	kWh	0.00	kWh
Water	0	MMgal	0.00	gal
Wastewater	0	MMgal	0.00	gal
Cooling Water	0	MMbtu	0.00	MMbtu
Compressed Air	0	1000 scf	0.00	scf
Solid Waste Disposal	0	tons	0.00	tons
SOx Reducing catalyst	91.25	tons	0.25	tons
Plot Space Needed	0	sf		
1 Truck Hauling Away Solid Waste	0	round trip miles	0.00	round trip miles
1 Truck Delivering SOx Reducing Catalyst[4]	1,600	round trip miles	400.00	round trip miles
No. of Trucks Hauling Away Solid Waste	0	trucks	0	truck
No. of Trucks Delivering SOx Reducing Catalyst	4	trucks	1	truck

[1]Assumes that one 10,000 gallon capacity storage tank will be installed for TG-10 storage. It will take 1 truck to deliver one year's worth of TG-10 solution, but the peak would be one truck per day.

4,000 gal/year x 1 truck/6,000 gallons = 0.67 trucks/year

[2]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of sulfur; the peak would be one truck per day.

10.35 long tons/yr Sulfur x 2,240 lbs/long ton = 23,184 lbs/yr x 1 ton/2000 lbs = 11.59 tons/yr x 1 truck/25 tons = 0.46 trucks/year to haul extra sulfur away to a buyer

[3]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 0 trucks to haul away one year's worth of solid waste.

[4]Assumes that one 25-ton truck will deliver catalyst. It will take 4 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.
One bulk catalyst truck can transport 25 tons.

Facility ID	Electricity Needed to Produce NaOH* (kWh/day)
A	1826
B	2653
C	0
D	994
E	1019
F	4585
G	6585
H	7631
I	1791
J	2939
K	0
TOTAL	30023

NaOH @ 50% solution density = 12.747 lb/gal
Mv for NaOH solution = 24.8 lb/lbmol
Vapor Pressure for NaOH = 2.18 mmHg at 29.4oC or 85oF = 0.042 psia
Loading Temperature = 85oF to 100oF (544.67oR to 559.67oR)
Breathing Loss = 3 * Filling Loss

Filling Loss:

$$E_{Loading}, \, lb/day = (12.46)\frac{(S)(P)(M)(Q)}{T}$$ where:

S = saturation factor (dimensionless; obtained from Table 5.2-1 in AP-42)
= 1.45 (Splash loading: dedicated normal service)
P = vapor pressure of the material loaded at temperature T (psia)
M = vapor molecular weight (lb/lb-mole)
Q = volume of material loaded (1,000 gal/day)
T = temperature of liquid loaded (°R).

*It takes approximately 2,500 kWh to produce one metric ton of NaOH.
Thus, approximately 22,444 kWh per day of additional electricity may be needed to produce additional NaOH to meet the needs of the proposed project, calculated as follows:

$$\frac{9.9 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = 22{,}444 \text{ kWh/day}$$

Filling Loss:

$$E_{Loading}, {}^{lb}/_{day} = (12.46)\frac{(S)(P)(M)(Q)}{T}$$ where:

S = saturation factor (dimensionless; obtained from Table 5.2-1 in AP-42)
= 1.45 (Splash loading: dedicated normal service)
P = vapor pressure of the material loaded at temperature T (psia)
M = vapor molecular weight (lb/lb-mole)
Q = volume of material loaded (1,000 gal/day)
T = temperature of liquid loaded (°R).

*It takes approximately 2,500 kWh to produce one metric ton of NaOH.
Thus, approximately 12,361 kWh per day of additional electricity may be needed to produce additional NaOH to meet the needs of the proposed project, calculated as follows:

$$\frac{5.45 \text{ tons NaOH}}{\text{Day}} \times \frac{2{,}000 \text{ lbs}}{\text{ton}} \times \frac{1 \text{ metric ton}}{2{,}205 \text{ lbs}} \times \frac{2{,}500 \text{ kWh}}{1 \text{ metric ton of NaOH produced}} = 12{,}361 \text{ kWh/day}$$

1 Truck Delivering NaOH[3]	400	round trip miles	50.00	round trip miles
No. of Trucks Hauling Away Solid Waste	12	trucks	1	truck
No. of Trucks Delivering NaOH	8	trucks	1	truck

[1]Assumes that the existing DEA amine storage tank can be used for Sulfinol storage.

[2]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 12 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
280 tons/yr solid waste x 1 truck/25 tons = 11.2 trucks/year to haul extra solid waste away for recycling

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 8 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.

294 tons/yr NaOH x 2,000 lbs/ ton = 328,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 46,045 gal/year x 1 truck/6,000 gallons = 7.67 trucks/year

Facility A estimated that a wet gas scrubber would generate 40 million gals per year wastewater = 109,589 gals per day.
Facility A has two distinct wastewater systems. System One is the un-segregated system, which handles water from cooling towers, boiler blowdowns, and stormwater.
This wastewater receives primary treatment, the maximum capacity for this system is 5000 gpm; the facility is currently running at about 3000 gpm.
System Two is the segregated system, which handles process water. This wastewater receives primary and secondary (biological) treatment.
The maximum capacity for this system is 2000 gpm; the facility is currently running at about 1800 gpm.
Facility A has some wastewater storage capacity to handle surges due to storms and upsets.

GHG Activity	Amount	Units	GHG Emissions Source	CO2 (MT/yr)	N2O (MT/yr)	CH4 (MT/yr)	Total CO2e (MT/yr)
natural gas use	-0.0056	MMscf/day	Natural Gas GHGs	-110.98	-0.0006	0.00	-111
electricity - increased use	30.9330	MWh/day	Electricity GHGs	5632.47	0.0000	0.00	5,632
water - increased use	0.0795	MMgal/day	Water Conveyance GHGs	10.10	0.0001	0.0001	10
wastewater - increased generation	0.0384	MMgal/day	Wastewater Processing GHGs	4.88	0.0000	0.0001	5
temporary construction activities[3]	1164.3504	MT/year	Construction GHGs in CO2e				39
operational truck trips	28.8876	MT/year	Operation GHGs in CO2e				29
						TOTAL CO2e	5,604

Note: The mitigation calculations assume that 100% of the total water demand for this facility can potentially be supplied by recycled water.

Facility A already accesses recycled water and will have increased future access to recycled water.

GHG Emission Factors:
1 metric ton (MT) = 2,205 pounds
120,000 lb CO2/MMscf fuel burned
0.64 lb N20/MMscf fuel burned
2.3 lb CH4/MMscf fuel burned
1,110 lb CO2e/MWh for electricity when source of power is not identified
(CEC, September 6, 2007 - Reporting and Verification of Greenhouse Gas Emissions in the Electricity Sector)
12,700 kWh/MMgallons for electricity use for water conveyance - potable water
1,200 kWh/MMgallons for electricity use for water conveyance - recycled water as mitigation
640 lb CO2/MWh for electricity use due to water conveyance
0.0067 lb CH4/MWh for electricity use due to water conveyance
0.0037 lb N2O/MWh for electricity use due to water conveyance

[3] GHGs from temporary construction activities are amortized over 30 years.

ALTERNATIVE C - OPTION 1: FACILITY B

Module 3A: FCCU

M1: Belco wet gas scrubber			**Facility B**	
Utility/Infrastructure	Annual Usage		Daily Usage	
Natural Gas	0	MMbtu	0.00	MMbtu
Electricity	12,080,000	kWh	33095.89	kWh
Water	28	MMgal	76712.33	gal
Wastewater	13	MMgal	35616.44	gal
Cooling Water	410	MMbtu	1.12	MMbtu
Compressed Air	440	1000 scf	1205.48	scf
Solid Waste Disposal	400	tons	1.10	tons
NaOH (50%)	427	tons	1.17	tons
Plot Space needed	2000	sf		
1 Truck Hauling Away Solid Waste[1]	6400	round trip miles	400.00	round trip miles
1 Truck Delivering NaOH[2]	600	round trip miles	50.00	round trip miles
No. of Trucks Hauling Away Solid Waste	16	trucks	1	truck
No. of Trucks Delivering NaOH	12	trucks	1	truck

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 16 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
400 tons/yr solid waste x 1 truck/25 tons = 16 trucks/year to haul extra solid waste away for recycling
This facility either sends its solid waste to a Class III landfill for disposal which is 80.64 miles (one-way) away or to a cement plant for recycling which is.67.48 miles (one-way) away.
However, the cement plant has shut-down its kilns on 11/20/2009 so the solid waste may be sent a different cement kiln further away or out of state (a maximum of 200 miles, one-way to the California/Arizona border).

[2]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 12 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
427 tons/yr NaOH x 2,000 lbs/ ton = 854,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 66,875 gal/year x 1 truck/6,000 gallons = 11.1 trucks/year

					12	Annual trucks			Annual Trucks

GRAND TOTALS (during Operation)

Note: This calculation takes into account the electricity needed to make 0.44 tons per day of NaOH to satisfy demand (994 kWh/day).

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 5 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.
110 tons/yr solid waste x 1 truck/25 tons = 4.46 trucks/year to haul extra solid waste away for recycling

[2]It will take one truck to deliver one year's worth of Merox catalyst; the peak would be one truck per day.

Merox is delivered by truck from Chicago. The distance from the California/Nevada border to this facility is approximately 250 miles, one-way.

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 5 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
160 tons/yr NaOH x 2,000 lbs/ ton = 320,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,059 gal/year x 1 truck/6,000 gallons = 4.2 trucks/year

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of sulfur; the peak would be one truck per day.
11 long tons/yr Sulfur x 2,240 lbs/long ton = 24,640 lbs/yr x 1 ton/2000 lbs = 12.32 tons/yr x 1 truck/25 tons = 0.49 trucks/year to haul extra sulfur away to a buyer

No. of Trucks Delivering Merox	1	trucks	1	truck
No. of Trucks Delivering NaOH	5	trucks	1	truck
No. of Trucks Hauling Sulfur Away	1	trucks	1	truck

SOx Reducing Additive

Utility/Infrastructure	Facility D Annual Usage		Facility D Daily Usage	
Natural Gas	0	MMbtu	0.00	MMbtu
Electricity	0	kWh	0.00	kWh
Water	0	MMgal	0.00	gal
Wastewater	0	MMgal	0.00	gal
Cooling Water	0	MMbtu	0.00	MMbtu
Compressed Air	0	1000 scf	0.00	scf
Solid Waste Disposal	0	tons	0.00	tons
SOx Reducing catalyst	91.25	tons	0.25	tons
Plot Space Needed	0	sf		
1 Truck Hauling Away Solid Waste[5]	0	round trip miles	0.00	round trip miles
1 Truck Delivering SOx Reducing Catalyst[6]	1,600	round trip miles	400.00	round trip miles
No. of Trucks Hauling Away Solid Waste	0	trucks	0	truck
No. of Trucks Delivering SOx Reducing Catalyst	4	trucks	1	truck

[1]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take an extra 5 trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.

110 tons/yr solid waste x 1 truck/25 tons = 4.46 trucks/year to haul extra solid waste away for recycling

[2]It will take one truck to deliver one year's worth of Merox catalyst; the peak would be one truck per day.

Merox is delivered by truck from Chicago. The distance from the California/Nevada border to this facility is approximately 250 miles, one-way.

[3]Assumes that one 10,000 gallon capacity storage tank will be installed for NaOH storage. It will take 5 trucks to deliver one year's worth of NaOH 50% solution, but the peak would be one truck per day.
160 tons/yr NaOH x 2,000 lbs/ ton = 320,000 lbs/yr x 1 gal NaOH @ 50%/12.77 lbs = 25,059 gal/year x 1 truck/6,000 gallons = 4.2 trucks/year

[4]Assumes Hauling Sulfur away in a 25 ton capacity truck. It will take 1 extra truck to haul away one year's worth of sulfur; the peak would be one truck per day.
11 long tons/yr Sulfur x 2,240 lbs/long ton = 24,640 lbs/yr x 1 ton/2000 lbs = 12.32 tons/yr x 1 truck/25 tons = 0.49 trucks/year to haul extra sulfur away to a buyer

[5]Assumes Hauling Solid Waste away in a 25 ton capacity truck. It will take no extra trucks to haul away one year's worth of solid waste, but the peak would be one truck per day.

[6]Assumes that one 25-ton truck will deliver catalyst. It will take 4 trucks to deliver one year's worth of catalyst, but the peak would be one truck per day.
One bulk catalyst truck can transport 25 tons.

GRAND TOTALS (during Operation)

(909) 396-2000 • www.aqmd.gov

SUBJECT: **NOTICE OF PREPARATION OF A DRAFT ENVIRONMENTAL ASSESSMENT**

PROJECT TITLE: **PROPOSED AMENDED REGULATION XX: REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM)**

In accordance with the California Environmental Quality Act (CEQA), the South Coast Air Quality Management District (SCAQMD), as the Lead Agency, has prepared this Notice of Preparation (NOP) and Initial Study (IS). This NOP serves two purposes: 1) to solicit information on the scope of the environmental analysis for the proposed project, and 2) to notify the public that the SCAQMD will prepare a Draft Environmental Assessment (EA) to further assess potential environmental impacts that may result from implementing the proposed project.

This letter, NOP and the attached IS are not SCAQMD applications or forms requiring a response from you. Their purpose is simply to provide information to you on the above project. If the proposed project has no bearing on you or your organization, no action on your part is necessary.

Comments focusing on your area of expertise, your agency's area of jurisdiction, or issues relative to the environmental analysis should be addressed to Ms. Barbara Radlein (c/o CEQA) at the address shown above, or sent by FAX to (909) 396-3324 or by e-mail to bradlein@aqmd.gov. Comments must be received no later than 5:00 PM on Tuesday, July 21, 2009. Please include the name and phone number of the contact person for your agency. Questions relative to the proposed amended regulation should be directed to Ms. Minh Pham at (909) 396-2613.

The Public Hearing for the proposed amended regulation is scheduled for November 6, 2009. (Note: Public meeting dates are subject to change).

Date: June 18, 2009 **Signature:** Steve Smith

NOTICE OF PREPARATION OF A DRAFT ENVIRONMENTAL ASSESSMENT

Project Title:
Draft Environmental Assessment for Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)

Project Location:
South Coast Air Quality Management District (SCAQMD) area of jurisdiction consisting of the four-county South Coast Air Basin (Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin and the Mojave Desert Air Basin

Description of Nature, Purpose, and Beneficiaries of Project:
SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM), Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to reduce the allowable SOx emission limits based on current Best Available Retrofit Control Technology (BARCT) for the following industrial equipment and processes: 1) fluid catalytic cracking units (FCCUs); 2) refinery boilers and heaters; 3) sulfur recovery – tail gas treatment units; 4) sulfuric acid manufacturing process; 5) container glass manufacturing process; 6) coke calcining; and, 7) portland cement manufacturing. Additional amendments are proposed to establish procedures and criteria for reducing RECLAIM Trading Credits (RTCs) and RTC adjustment factors for year 2013 and later. Other minor changes are proposed for clarity and consistency throughout the regulation. The Initial Study identifies the topics of aesthetics, air quality, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic as areas that may be adversely affected by the proposed project. Impacts to these environmental areas will be further analyzed in the Draft EA.

Lead Agency:	**Division:**
South Coast Air Quality Management District	Planning, Rule Development and Area Sources

Initial Study and all supporting documentation are available at:	**or by calling:**	**or by accessing the SCAQMD's website at:**
SCAQMD Headquarters 21865 Copley Drive Diamond Bar, CA 91765	(909) 396-2039	http://www.aqmd.gov/ceqa/aqmd.html

The Public Notice of Preparation is provided through the following:

☑ Los Angeles Times (June 19, 2009) ☑ AQMD Website ☑ AQMD Mailing List

Initial Study 30-day Review Period:
June 19, 2009 – July 21, 2009

Scheduled Public Meeting Dates (subject to change):
Public Workshop/CEQA Scoping Meeting: June 23, 2009, 2:00pm to 4:00pm; SCAQMD Headquarters
SCAQMD Governing Board Hearing: November 6, 2009, 9:00 a.m.; SCAQMD Headquarters

The proposed project may have statewide, regional or areawide significance; therefore, a CEQA scoping meeting is required (pursuant to Public Resources Code §21083.9(a)(2)).

INTRODUCTION

The California Legislature created the South Coast Air Quality Management District (SCAQMD) in 1977[1] as the agency responsible for developing and enforcing air pollution control rules and regulations in the South Coast Air Basin (Basin) and portions of the Salton Sea Air Basin and Mojave Desert Air Basin, referred to herein as the district. By statute, the SCAQMD is required to adopt an air quality management plan (AQMP) demonstrating compliance with all federal and state ambient air quality standards for the district[2]. Furthermore, the SCAQMD must adopt rules and regulations that carry out the AQMP[3]. The 2007 AQMP concluded that major reductions in emissions of volatile organic compounds (VOCs), oxides of sulfur (SOx) and oxides of nitrogen (NOx) are necessary to attain the air quality standards for ozone (the key ingredient of smog) and particulate matter (PM10 and PM2.5). Ozone, a criteria pollutant which has been shown to adversely affect human health, is formed when VOCs react with NOx in the atmosphere. VOCs, NOx, SOx (especially sulfur dioxide) and ammonia also contribute to the formation of PM10 and PM2.5.

The Basin is designated by the United States Environmental Protection Agency (EPA) as a non-attainment area for PM2.5 emissions because the federal PM2.5 standards have been exceeded. For this reason, the SCAQMD is required to evaluate all feasible control measures in order to reduce direct PM2.5 emissions, as well as PM2.5 precursors, such as NOx and SOx. The 2007 AQMP contains a multi-pollutant control strategy to achieve attainment with the federal PM2.5 standards with NOx and SOx reductions identified as the two most effective tools in reaching attainment with the PM2.5 standards.

As part of this ongoing PM2.5 reduction effort, SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM) to achieve additional SOx emission reductions as outlined in the 2007 AQMP in Control Measure CMB-02: Further SOx Reduction for RECLAIM (CM #2007CMB-02). Amendments are proposed to Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to address Best Available Retrofit Control Technology (BARCT) requirements, which may require installation or modification of SOx emission control equipment. Other changes proposed are administrative in nature and include minor clarifications for continuity.

The primary focus of the proposed project is to bring the SOx RECLAIM program up-to-date with the latest BARCT requirements to achieve, at a minimum, the proposed SOx emission reductions in CM #2007CMB-02 (at least 2.9 tons per day by compliance year 2014). The proposed project may achieve additional SOx emission reductions depending on the actual BARCT SOx emission control efficiencies. The proposed project will affect the following types of equipment and processes at SOx RECLAIM facilities: 1) petroleum coke calciners; 2) cement kilns; 3) coal-fired boiler (cogeneration); 4) container glass melting furnace; 5) diesel combustion; 6) fluid catalytic cracking units (FCCUs); 7) refinery boilers/heaters; 8) sulfur recovery units/tail gas treatment units; and, 9) sulfuric acid manufacturing. Additional amendments are proposed to establish procedures and criteria for reducing RECLAIM Trading Credits (RTCs) and RTC adjustment factors for year 2013 and later. Other minor changes are proposed for clarity and consistency throughout the proposed amended rules.

---

[1] The Lewis-Presley Air Quality Management Act, 1976 Cal. Stats., ch 324 (codified at Health & Safety Code, §§40400-40540).
[2] Health & Safety Code, §40460 (a).
[3] Health & Safety Code, §40440 (a).

The proposed project is estimated to reduce at least 2.9 tons per day of SOx emissions or more by 2014. Despite this projected environmental benefit to air quality, this Initial Study, prepared pursuant to the California Environmental Quality Act (CEQA), identifies the following environmental topics as areas that may be adversely affected by the proposed project: aesthetics, air quality, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic. A Draft Environmental Assessment (EA) will be prepared to analyze further whether the potential impacts to these environmental topics are significant. Any other potentially significant environmental impacts identified through this Notice of Preparation/Initial Study process will also be analyzed in the Draft EA.

CALIFORNIA ENVIRONMENTAL QUALITY ACT

The proposed amendments to Regulation XX are considered a "project" as defined by CEQA. CEQA requires that the potential adverse environmental impacts of proposed projects be evaluated and that methods to reduce or avoid identified significant adverse environmental impacts of these projects be implemented if feasible. The purpose of the CEQA process is to inform the SCAQMD's Governing Board, public agencies, and interested parties of potential adverse environmental impacts that could result from implementing the proposed project and to identify feasible mitigation measures or alternatives, when an impact is significant.

California Public Resources Code §21080.5 allows public agencies with regulatory programs to prepare a plan or other written documents in lieu of an environmental impact report once the Secretary of the Resources Agency has certified the regulatory program. The SCAQMD's regulatory program was certified by the Secretary of Resources Agency on March 1, 1989, and is codified as SCAQMD Rule 110. Pursuant to Rule 110 (the rule which implements the SCAQMD's certified regulatory program), SCAQMD is preparing a Draft Environmental Assessment (EA) to evaluate potential adverse impacts from the proposed project.

The SCAQMD as Lead Agency for the proposed project, has prepared this Initial Study (which includes an Environmental Checklist and project description). The Environmental Checklist provides a standard evaluation tool to identify a project's adverse environmental impacts. The Initial Study is also intended to provide information about the proposed project to other public agencies and interested parties prior to the release of the Draft Environmental Assessment (EA). Written comments on the scope of the environmental analysis will be considered (if received by the SCAQMD during the 30-day review period) when preparing the Draft EA.

PROJECT LOCATION

The proposed amendments to Regulation XX would apply to equipment and processes operated at SOx RECLAIM facilities located throughout the entire SCAQMD jurisdiction. The SCAQMD has jurisdiction over an area of approximately 10,743 square miles, consisting of the four-county South Coast Air Basin (Basin) (Orange County and the non-desert portions of Los Angeles, Riverside and San Bernardino counties), and the Riverside County portions of the Salton Sea Air Basin (SSAB) and Mojave Desert Air Basin (MDAB). The Basin, which is a subarea of the SCAQMD's jurisdiction, is bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto mountains to the north and east. It includes all of Orange County and the nondesert portions of Los Angeles, Riverside, and San Bernardino counties. The Riverside County portion of the SSAB is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley. The federal nonattainment area (known as the Coachella Valley Planning Area) is a subregion of Riverside County and the

SSAB that is bounded by the San Jacinto Mountains to the west and the eastern boundary of the Coachella Valley to the east (Figure 1-1).

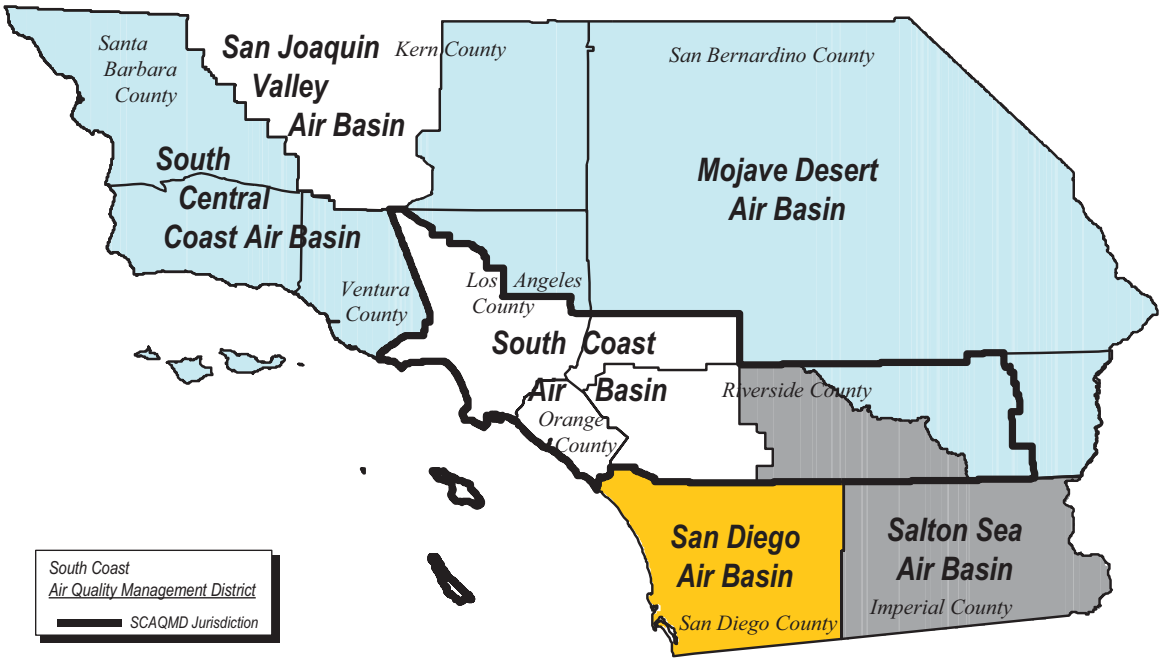

Figure 1-1
South Coast Air Quality Management District

PROJECT BACKGROUND

Adopted in October 1993, Regulation XX – RECLAIM, is comprised of 11 rules which contain a declining cap and trade mechanism to reduce NOx and SOx emissions from the largest stationary sources in the Basin. The portion of Regulation XX that focuses on reducing NOx emissions is referred to as "NOx RECLAIM" while the portion that focuses on reducing SOx emissions is referred to as "SOx RECLAIM." Regulation XX contains applicability requirements, NOx and SOx facility allocations, general requirements, as well as monitoring, reporting, and recordkeeping requirements for NOx and SOx sources located at RECLAIM facilities. The RECLAIM program started with 41 SOx facilities and 392 NOx facilities, but by the end of the 2005 compliance year, the program is populated with 33 SOx facilities and 304 NOx facilities. The reduction in the number of facilities participating in the RECLAIM program since inception has been primarily due to facility shutdowns.

Under the SOx RECLAIM program, the RECLAIM facilities were issued annual allocations of SOx emissions (also known as facility caps), which declined annually from 1993 until 2003 and remained constant after 2003. In 1993, annual allocations were issued to the RECLAIM facilities and the facility cap reflected BARCT in effect at that time. SCAQMD staff has since

conducted a BARCT reassessment for NOx in 2005, but not for SOx. A BARCT reassessment is now necessary for SOx RECLAIM to assure that the participating facilities will continue to achieve emission reductions as expeditiously as possible. Under the RECLAIM program, the facilities have the flexibility to install air pollution control equipment, change method of operations, or purchase RTCs to meet BARCT levels.

PROJECT OBJECTIVE

The primary focus of the proposed project is to bring the SOx RECLAIM program up-to-date with the latest BARCT requirements to achieve, at a minimum, the proposed SOx emission reductions in CM #2007CMB-02 (at least 2.9 tons per day by compliance year 2014). Another objective of the proposed project is to establish procedures and criteria for reducing RTCs and RTC adjustment factors for year 2013 and later. Other minor changes are proposed for clarity and consistency throughout the proposed amended rules. The proposed project is estimated to reduce at least 2.9 tons per day of SOx emissions by 2014, which will assist the SCAQMD with attaining state and federal ambient air quality standards for PM10 and PM2.5.

PROJECT DESCRIPTION

The proposed project will affect the following types of equipment and processes at 12 SOx RECLAIM facilities: 1) petroleum coke calciners; 2) cement kilns; 3) coal-fired boiler (cogeneration); 4) container glass melting furnace; 5) diesel combustion; 6) fluid catalytic cracking units; 7) refinery boilers/heaters; 8) sulfur recovery units/tail gas treatment units; and, 9) sulfuric acid manufacturing. The following is a summary of the key proposed amendments to Rule 2002. Other minor changes are also proposed for clarity and consistency throughout the rule. A copy of the proposed amended rule can be found in Appendix A.

Proposed Amended Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx)

<u>RECLAIM Allocations - subdivision (b)</u>

Cross-references in paragraph (b)(3) have been modified for clarity and continuity with the proposed revisions in subdivision (f) regarding annual allocations for NOx and SOx and adjustments to RTC holdings.

<u>Establishment of Starting Allocations - subdivision (c)</u>

Cross-references to procedures for reducing SOx RTCs for compliance year 2014 and later have been added to paragraph (c)(3) and subparagraph (c)(5)(C).

<u>Annual Allocations for NOx and SOx and Adjustments to RTC Holdings - subdivision (f)</u>

In accordance with the analysis prepared for Control Measure #2007CMB-02 in the 2007 AQMP which estimates an additional reduction in SOx RECLAIM emissions of 2.9 tons per day by 2014, new criteria, procedures, and adjustment factors for adjusting SOx RTC holdings have been added to paragraph (f)(2) in order to achieve these projected emission reductions from SOx RTC holders by compliance year 2013 and later. The actual amount of reductions will depend on the analysis of what is technically and economically feasible. It is expected that the adjustment factors for compliance year 2013 and later will be developed based on current BARCT evaluations and are expected to be within the range of three tons per day to eight tons per day. The proposed changes would also comply with the BARCT requirements applicable to market-based incentive programs. Specifically, the BARCT adjustment that will be made to

each facility's holdings will be implemented on a programmatic basis, with an equal percentage reduction to all RTC holdings beginning in compliance year 2013.

RECLAIM SOx 2014 BARCT – Table 4

New Table 4 has been added to Rule 2002 to establish BARCT for petroleum coke calciners, cement kilns and coal-fired boilers, container glass melting furnaces, diesel combustion, fluid catalytic cracking units, refinery boilers and heaters, sulfur recovery units/tail gas treatment units, and sulfuric acid manufacturing. Currently, Table 4 contains a list of the control technologies that could be used to achieve BARCT. However, Table 4 does not yet contain the BARCT emission rates, for all of the aforementioned equipment except diesel combustion, which has a limit of 15 parts per million by volume (ppmv) to be consistent with existent emission limits in SCAQMD Rule 431.2 – Sulfur Content of Liquid Fuels. Initial estimates show that a range of SOx emission reductions between three tons per day to eight tons per day are under consideration for the proposed project, but the actual amount of SOx reductions will depend on the analysis of what is technically and economically feasible. As the rule development process progresses, eventually Table 4 will contain BARCT emission rates appropriate to the basic equipment listed.

TECHNOLOGY OVERVIEW

SOx Emission Sources

The SOx RECLAIM program consists of 33 facilities as of the 2005 Compliance Year. Of these 33, 12 RECLAIM facilities represent the top emitters of SOx (i.e., emit 95 percent of the total SOx emissions from all RECLAIM facilities). For this reason, the proposed project will focus on reducing SOx emissions from these top emitters. They are:

- Six refineries: BP (Carson location); ConocoPhillips (Wilmington location); Chevron; ExxonMobil; Ultramar (also referred to as Valero); and, Equilon (also referred to as Tesoro)
- Two sulfuric acid plants: Rhodia Inc. and ConocoPhillips (Carson location)
- One coke calciner plant: BP (Wilmington location)
- One cement manufacturing plant: California Portland Cement
- Two container glass manufacturing plants: Owens-Brockway Glass Container Inc. and Saint-Gobain Containers Inc.

On an equipment/process basis, Table 1-1 shows the distribution of SOx emissions with respect to the equipment/processes at these 12 SOx RECLAIM facilities. These source categories are responsible for 80 percent of the facility emissions.

Table 1-1
Distribution of SOx Emissions at RECLAIM Facilities By Equipment/Process

Equipment/Process	Percentage of Emissions
FCCUs	33%
Refinery Process Heaters and Boilers	31%
Sulfuric Acid Manufacturing	12%
Sulfur Recovery Units and Tail Gas Units	10%
Cement Kilns and Glass Melting Furnaces	7%
Other Miscellaneous Processes/Equipment	7%

Reference: Baseline emissions from Compliance Year 2005

Of the 12 facilities, six refineries operate one FCCU each, one sulfur recovery and tail gas unit each, and a multitude of refinery process heaters and boilers. The quantity of SOx emissions from the six refineries alone comprise approximately 74 percent of the total SOx emitted from the 12 RECLAIM facilities that will be affected by the proposed project. The remaining six facilities emit 26 percent of the total.

To appreciate the mechanics of SOx control equipment and techniques, it is necessary to first understand how SOx emissions are generated from the equipment and processes listed in Table 1-1.

FCCUs

The purpose of a FCCU at a refinery is to convert or "crack" heavy oils (hydrocarbons), with the assistance of a catalyst, into gasoline and lighter petroleum products. Each FCCU consists of three main components: a reaction chamber, a catalyst regenerator and a fractionator. All six refineries each operate one FCCU.

The cracking process begins in the reaction chamber where fresh catalyst is mixed with pre-heated heavy oils (crude) known as the fresh feed. The catalyst typically used for cracking is a fine powder made up of tiny particles with surfaces covered by several microscopic pores. A high heat-generating chemical reaction occurs that converts the heavy oil liquid into a cracked hydrocarbon vapor mixed with catalyst. As the cracking reaction progresses, the cracked hydrocarbon vapor is routed to a distillation column or fractionator for further separation into lighter hydrocarbon components than crude such as light gases, gasoline, light gas oil, and cycle oil.

Towards the end of the reaction, the catalyst surface becomes inactive or spent because the pores are gradually coated with a combination of heavy oil liquid residue and solid carbon (coke), thereby reducing its efficiency or ability to react with fresh heavy liquid oil in the feed. To prepare the spent catalyst for re-use, the remaining oil residue is removed by steam stripping. The spent catalyst is later cycled to the second component of the FCCU, the regenerator, where hot air burns the coke layer off of the surface of each catalyst particle to produce reactivated or regenerated catalyst. Subsequently, the regenerated catalyst is cycled back to the reaction chamber and mixed with more fresh heavy liquid oil feed. Thus, as the heavy oils enter the cracking process through the reaction chamber and exit the fractionator as lighter components, the catalyst continuously circulates between the reaction chamber and the regenerator.

During the regeneration cycle, large quantities of catalyst are lost in the form of catalyst fines or particulates thus making FCCUs a major source of primary particulate emissions at refineries. In addition, particulate precursor emissions such as SOx (because crude oil naturally contains sulfur) and NOx, additional secondary particulates (i.e., formed as a result of various chemical reactions), plus carbon monoxide (CO) and carbon dioxide (CO2) are produced due to coke burn-off during the regenerator process.

The potential available control technologies to reduce SOx emissions from a FCCU are:

1. Processing of low sulfur feed stocks;
2. Feed hydro-treating;
3. Flue gas scrubbing via wet gas scrubbers;

4. Using SOx reducing catalyst; or,
5. Using a combination of these control technologies.

The type of SOx control option to be utilized in response to the proposed project for FCCUs will depend on each refinery's individual operations and the current control technologies and techniques in place. For example, all six refineries already process low sulfur feed stocks and utilize feed hydrotreating for their FCCUs. Thus, the Draft EA will evaluate the possibility that each refinery may rely on wet gas scrubbers or SOx reducing additives or a combination of both control options in order to comply with the BARCT requirements for the FCCU portion of the proposed project.

Refinery Process Heaters and Boilers

Refinery process heaters and boilers are used extensively throughout various processes in refinery operations such as distillation, hydrotreating, fluid catalytic cracking, alkylation, reforming, and delayed coking. There are approximately 300 refinery process heaters and boilers operating throughout the six aforementioned refineries and the top 16 emitters in this category collectively emitted about one ton per day of SOx in 2005. Refinery process heaters and boilers are primarily fueled by refinery gas, one of several products generated at the refinery. In addition, most of the refinery process heaters and boilers are designed to also operate on natural gas, but liquid or solid fuels are rarely used.

SOx is created from the combustion of fuel that contains sulfur or sulfur compounds. To reduce SOx emissions from these refinery process heaters and boilers, the refinery operators can opt to use lower sulfur-containing fuels to reduce the sulfur input on the front end (e.g., fuel gas treatment), or to install flue gas scrubber (wet scrubber) to reduce SOx emissions in the flue gas after it exits the refinery process heaters and boilers on the back end. The Draft EA will evaluate the possibility that each refinery may rely on either control option in order to comply with the refinery process heaters and boilers portion of the proposed project.

Sulfur Recovery Units and Tail Gas Units

Because sulfur is a naturally occurring and undesirable component of crude oil, refineries employ a sulfur recovery system to maximize sulfur removal. A typical sulfur removal or recovery system will include a sulfur recovery unit (e.g., Claus unit) followed by a tail gas treatment unit (e.g., amine treating) for maximum removal of hydrogen sulfide (H2S). A Claus unit consists of a reactor, catalytic converters and condensers. Two chemical reactions occur in a Claus unit. The first reaction occurs in the reactor, where a portion of H2S reacts with air to form sulfur dioxide (SO2) followed by a second reaction in the catalytic converters where SO2 reacts with H2S to form liquid elemental sulfur. Side reactions producing carbonyl sulfide (COS) and carbon disulfide (CS2) can also occur. These side reactions are problematic for Claus plant operators because COS and CS2 cannot be easily converted to elemental sulfur and carbon dioxide. Liquid sulfur is recovered after the final condenser. The combination of two converters with two condensers in series will generally remove as much as 95 percent of the sulfur from the incoming acid gas. To increase removal efficiency, some newer sulfur recovery units may be designed with three to four sets of converters and condensers.

To recover the remaining sulfur compounds after the final pass through the last condenser, the gas is sent to a tail gas treatment process such as a SCOT or Wellman-Lord treatment process. For example, the SCOT tail gas treatment is a process where the tail gas is sent to a catalytic reactor and the sulfur compounds in the tail gas are converted to H2S. The H2S is absorbed by a

solution of amine or diethanol amine (DEA) in the H2S absorber, steam-stripped from the absorbent solution in the H2S stripper, concentrated, and recycled to the front end of the sulfur recovery unit. This approach typically increases the overall sulfur recovery efficiency of the Claus unit to 99.8 percent or higher. However, the fresh acid gas feed rate to the sulfur recovery unit is reduced by the amount of recycled stream, which reduces the capacity of the sulfur recovery unit. The residual H2S in the treated gas from the absorber is typically vented to a thermal oxidizer where it is oxidized to sulfur dioxide (SO2) before venting to the atmosphere.

The Wellman-Lord tail gas treatment process is when the sulfur compounds in the tail gas are first incinerated to oxidize to SO2. After the incinerator, the tail gas enters a SO2 absorber, where the SO2 is absorbed in a sodium sulfite (Na_2SO_3) solution to form sodium bisulfite ($NaHSO_3$) and sodium pyrosulfate ($Na_2S_2O_5$). The absorbent rich in SO_2 is then stripped, and the SO_2 is recycled back to the beginning of the Claus unit. The residual sulfur compounds in the treated tail gas from the SO2 absorber is then vented to a thermal oxidizer where it is oxidized to SO2 before venting to the atmosphere.

There are three main strategies that can be employed to further reduce SO2 emissions from each sulfur recovery/tail gas treatment unit operating at the six refineries: 1) increase the efficiency of the sulfur recovery unit; 2) improve the efficiency of the tail gas treatment process; and, 3) install a wet gas scrubber as an alternative to the thermal oxidizer[4]. The type of SOx control option to be utilized in response to this portion of the proposed project will depend on each refinery's individual operations and the current control technologies and techniques in place. Thus, the Draft EA will evaluate the possibility that each refinery may rely on the SOx control strategies identified above in order to comply with the sulfur recovery/tail gas treatment unit portion of the proposed project.

Sulfuric Acid Manufacturing

Sulfuric acid is a commodity chemical that is used in manufacturing phosphate and nitrogen fertilizers, detergents, paper, rust removers. It is also used extensively in automobile manufacturing, metal smelting, water treatment and oil refining processes.

There are two facilities in the Basin that manufacture sulfuric acid. The sulfuric acid manufacturing process includes three basic operations. First, the sulfur in the feedstock is oxidized to sulfur dioxide (SO2) in a furnace. The SO2 is then catalytically oxidized (using vanadium as the catalyst) to sulfur trioxide (SO3) in a multi-staged catalytic reactor (or converter). Lastly, the sulfur trioxide is absorbed (e.g., combined with water) to create a strong sulfuric acid (H_2SO_4) solution.

In a dual or two-stage absorption process, the SO3 gas formed from the primary converter is sent to a first absorber where most of the SO3 is removed to form H_2SO_4. The remaining unconverted SO2 and SO3 are directed to a secondary converter and absorber set to further remove H_2SO_4.

The conversion of SO2 to H_2SO_4 is an incomplete, exothermic reaction which means that there is always one to two percent of SO2 that does not get converted to H_2SO_4. The success of conversion is affected by the number of stages in the catalytic converter, the amount of catalyst used, temperature and pressure, and the concentrations of the reactants, SO2 and elemental

[4] All six refineries have thermal oxidizers at the end of their tail gas treatment units.

oxygen (O_2). The remaining SO2 in the exhaust gas stream from the absorbers is vented to ESPs, scrubbers, and mist eliminators to remove SO_2 and acid mist prior to venting to the atmosphere. Because the conversion of SO2 to H_2SO_4 is exothermic (e.g., produces a great deal of heat), the heat is recovered and converted into useful energy for operating steam-driven compressors, waste heat boilers, and heat exchangers. The Draft EA will evaluate the possibility that each sulfuric acid manufacturing facility may rely on wet gas scrubbers in order to comply with the BARCT requirements for this portion of the proposed project

Container Glass Melting Furnace

A container glass melting furnace is the main equipment used for manufacturing glass products, such as bottles, glass wares, pressed and blown glass, tempered glass, and safety glass. The manufacturing process consists of four phases: 1) preparation of the raw materials; 2) melting the mixture of raw materials in the furnace; 3) forming the desired shape; and, 4) finishing the final product. Raw materials, such as sand, limestone, and soda ash, are crushed and mixed with cullets (recycled glass pieces) to ensure homogeneous melting. The raw materials mixture is then conveyed to a continuous regenerative side-port melting furnace. As the mixture enters the furnace through a feeder, it melts and blends with the molten glass already in the furnace, and eventually flows to a refiner section, forming machine, and annealing ovens. The final products undergo inspection, testing, packaging and storage. Any damaged or undesirable glass is transferred back to be recycled as cullets.

SOx is generated from a container glass melting furnace in two ways: 1) during the decomposition of the sulfates in the raw materials; and, 2) from combusting fuel (that contains sulfur) to generate high heating values in the furnace. The container glass melting furnace contributes over 99 percent of the total SOx emissions from a glass manufacturing plant.

SOx emissions from a container glass melting furnace are typically controlled by a scrubber followed by a dry electrostatic precipitator (ESP) to control particulates. Two glass melting facilities are in the SOx RECLAIM program, but only one of these facilities is currently operating. The type of SOx control option to be utilized in response to the proposed project will depend on this facility's individual operations and the current control technologies and techniques in place. Thus, the Draft EA will evaluate the possibility that operators of the glass melting facility may rely on a wet gas scrubber or dry gas scrubber to further control SOx emissions in order to comply with the BARCT requirements for the FCCU portion of the proposed project.

Petroleum Coke Calciner

Petroleum coke, the heaviest portion of crude oil, cannot be recovered in the normal oil refinining process. Instead, it is processed in a delayed coker unit to generate a carbonaceous solid referred to as "green coke," a commodity. To improve quality of the product, if the green coke has a low metals content, it will be sent to a calciner to make calcined petroleum coke. Calcined petroleum coke can be used to make anodes for the aluminum, steel, and titanium smelting industry. If the green coke has a high metals content, it is used a fuel grade coke by the fuel, cement, steel, calciner and specialty chemicals industries.

The process of making calcined petroleum coke begins when the green coke feed from the delayed coker unit is screened and transported to the calciner unit where it is stored in a covered coke storage barn. The screened and dried green coke is introduced into the top end of a rotary kiln and is tumbled by rotation under high temperatures that range between 2,000 and 2,500

degrees Fahrenheit (^{o}F). The rotary kiln relies on gravity to move coke through the kiln countercurrent to a hot stream of combustion air produced by the combustion of natural gas or fuel oil. As the green coke flows to the bottom of the kiln, it rests in the kiln for approximately one additional hour to eliminate any remaining moisture, impurities, and hydrocarbons. Once discharged from the kiln, the calcined coke is dropped into a cooling chamber, where it is quenched with water, treated with de-dusting agents to minimize dust, carried by conveyors to storage tanks. Eventually, the calcined coke is transported by truck to the Port of Long Beach for export, or is loaded onto railcars for shipping to domestic customers.

Because sulfur is a naturally occurring and undesirable component of crude oil, it remains a component of the green coke after it exits the delayed coking unit. As the green coke is processed under high heat conditions in the rotary kiln, SOx emissions are generated. SOx is also generated from combusting fuel oil (that contains sulfur) to generate high heating values in the rotary kiln.

There is only one petroleum coke calciner in the Basin and the SOx emissions from the unit are controlled by a dry scrubber. The existing control system also includes a spray dryer, a reverse-air baghouse, a slurry storage system, a slurry circulating system, and a pneumatic conveying system. Calcium hydroxide (CaOH) slurry is the absorbing medium for SO2 control. The type of SOx control option to be utilized in response to the proposed project will depend on this facility's individual operations and the current control technologies and techniques in place. Thus, the Draft EA will evaluate the possibility that operators of the petroleum coke calcining facility may rely on a wet gas scrubber to further control SOx emissions in order to comply with the BARCT requirements for the petroleum coke calcining portion of the proposed project.

Cement Kiln and Coal-Fired Boiler

Of the two Portland cement manufacturing facilities located in the Basin, California Portland Cement Company (CPCC) and TXI Riverside Cement Company (TXI), the quantity of SOx emissions from CPCC at 100.5 tons per year is substantially greater than TXI's SOx emissions at 0.7 ton per year for compliance year 2005. Because the proposed project is directed at reducing emissions from the top 12 SOx emitters, the following discussion is limited to reducing SOx emissions at the CPCC facility.

CPCC manufactures gray Portland cement in two cement kilns and follows a four-step process of: 1) acquiring raw materials; 2) preparing the raw materials to be blended into a raw mix; 3) pyroprocessing of the raw mix to make clinker; and, 4) grinding and milling clinker into cement. The raw materials used for manufacturing cement include calcium, silica, alumina and iron, with calcium having the highest concentration. These raw materials are obtained from a limestone quarry for calcium, sand for silica; and shale and clay for alumina and silica.

The raw materials are crushed, milled, blended into a raw mix and stored. Primary, secondary and tertiary crushers are used to crush the raw materials until they are about ¾-inch or smaller in size. Raw materials are then conveyed to rock storage silos. Belt conveyors are typically used for this transport. Roller mills or ball mills are used to blend and pulverize raw materials into fine powder. Pneumatic conveyors are typically used to transport the fine raw mix to be stored in silos until it is ready to be pyroprocessed.

The pyroprocess in a kiln consists of three phases during which clinker is produced from raw materials undergoing physical changes and chemical reactions. The first phase in a kiln, the

drying and pre-heating zone, operates at a temperature between 70 ^{o}F and 1650 ^{o}F and evaporates any remaining water in the raw mix of materials entering the kiln. Essentially this is the warm-up phase which stabilizes the temperature of the refractory fire brick inside the mouth opening of the kiln. The second phase, the calcining zone, operates at a temperature between 1100 ^{o}F and 1650 ^{o}F and converts the calcium carbonate from the limestone in the kiln feed into calcium oxide and releases carbon dioxide. During the third phase, the burning zone operates on average at 2200 ^{o}F to 2700 ^{o}F (though the flame temperature can exceed 3400 ^{o}F) during which several reactions and side reactions occur. The first reaction is calcium oxide (produced during the calcining zone) with silicate to form dicalcium silicate and the second reaction is the melting of calcium oxide with alumina and iron oxide to form the liquid phase of the materials. Despite the high temperatures, the constituents of the kiln feed do not combust during pyroprocessing. As the materials move towards the discharge end of the kiln, the temperature drops and eventually clinker nodules form and volatile constituents, such as sodium, potassium, chlorides, and sulfates, evaporate. Any excess calcium oxide reacts with dicalcium silicate to form tricalcium silicate. The red hot clinker exits the kiln, is cooled in the clinker cooler, passes through a crusher and is conveyed to storage for protection from moisture. Since clinker is water reactive, if it gets wet, it will set into concrete.

Heat used in CPCC's kilns is supplied through the combustion of different fuels such as coal, coke, oil, natural gas, and discarded automobile tires. The combustion gases are vented to a baghouse for dust control, and the collected dust is returned to the process or recycled if they meet certain criteria, or is discarded to landfills. Post-combustion control for SOx is not currently used at CPCC.

In addition to the cement kilns, another potential source of SOx emissions at CPCC could be from the coal-fired steam boiler due to the high sulfur content in coal. While CPCC reported that the coal-fired steam boiler has not been in operation since 2002, CPCC may begin operating the boiler again in the near future if circumstances in energy costs or fuel sources change.

SOx emissions from the cement kilns and coal-fired boiler are generated from the following: 1) combustion of sulfur in the fuel; and, 2) oxidation of sulfides (e.g. pyrites) in the raw materials entering the cement kiln. Fuel switching, process alterations, dry and wet scrubbers are commercially available control technologies to reduce SOx emissions. The type of scrubber to be utilized in response to the proposed project will depend on this facility's individual operations and how it will function with the current control technologies and techniques in place at CPCC (e.g., the baghouse). Thus, the Draft EA will evaluate the possibility that operators of CPCC may rely on a wet gas scrubber or dry gas scrubber, or a hybrid of dry gas scrubber with a baghouse, to further control SOx emissions in order to comply with the BARCT requirements for the cement kiln and coal-fired boiler portion of the proposed project.

SOx Control Technologies

On an equipment/process basis, Table 1-2 shows the control technologies that will be considered as part of the BARCT analysis for the proposed project. The following discussions will elaborate on the various technologies listed in Table 1-2.

Table 1-2
BARCT Control Technologies Under Consideration
for SOx Emitting Equipment/Processes

Equipment/Process	BARCT Control Technology
Petroleum Coke Calciner	Wet Gas Scrubber
Cement Kilns and Coal-Fired Boiler	1. Dry Gas Scrubber 2. Wet Gas Scrubber 3. Combination of both
Container Glass Melting Furnaces	1. Dry Gas Scrubber 2. Wet Gas Scrubber
FCCUs	1. Wet Gas Scrubber 2. SOx Reducing Catalyst 3. Combination of both
Refinery Process Heaters and Boilers	1. Wet Gas Scrubber 2. Fuel Gas Treatment
Sulfuric Acid Manufacturing	Wet Gas Scrubber
Sulfur Recovery Units/Tail Gas Units	1. Wet Gas Scrubber 2. Selective Oxidation Catalyst

Wet Gas Scrubbers

Wet gas scrubbers are used to control both SOx and particulate emissions and can be installed on petroleum coke calciners, cement kilns and coal-fired boilers, container glass melting furnaces, FCCUs, refinery process heaters and boilers, sulfuric acid manufacturing, and sulfur recovery units/tail gas units. There are two types of wet gas scrubbers: 1) caustic-based non-regenerative wet gas scrubber; and, 2) regenerative wet gas scrubber. Both systems can be used to achieve below a 25 ppmv SOx outlet concentration.

In non-regenerative wet gas scrubbing, caustic soda (sodium hydroxide - NaOH) or other alkaline reagents, such as soda ash and magnesium hydroxide, are used as an alkaline absorbing reagent (absorbent) to capture SO2 emissions. The absorbent captures SO2 and sulfuric acid mist (H2SO4) and converts it to various types of sulfites and sulfates (e.g., NaHSO3, Na2SO3, and Na2SO4). The absorbed sulfites and sulfates are later separated by a purge treatment system and the treated water, free of suspended solids, is either discharged or recycled.

One example of the caustic-based non-regenerative scrubbing system is the proprietary Electro Dynamic Venturi (EDV) scrubbing system offered by BELCO Technologies Corporation. An EDV scrubbing system consists of three main modules: 1) a spray tower module; 2) a filtering module; and, 3) a droplet separator module. The flue gas enters the spray tower module, which is an open tower with multiple layers of spray nozzles. The nozzles supply a high density stream of caustic water that is directed in a countercurrent flow to the gas flow and encircles, encompasses, wets, and saturates the flue gas. Multiple stages of liquid/gas absorption occur in the spray tower module and SO2 and acid mist are captured and converted to sulfites and sulfates. Large particles in the flue gas are also removed by impaction with the water droplets.

The flue gas saturated with heavy water droplets continues to move up the wet scrubber to the filtering module where the flue gas reaches super-saturation. At this point, water continues to

condense and the fine particles in the gas stream begin to cluster together, to form larger and heavier groups of particles. Next, the flue gas, super-saturated with heavy water droplets, enters the droplet separator module causing the water droplets to impinge on the walls of parallel spin vanes and drain to the bottom of the scrubber.

The spent caustic water purged from the wet scrubber is later processed in a purge treatment unit. The purge treatment unit contains a clarifier that removes suspended solids for disposal. The effluent from the clarifier is oxidized with agitated air which helps convert sulfites to sulfates and also reduces the chemical oxygen demand (COD) so that the effluent can be safely discharged to a waste water system.

A regenerative wet gas scrubber removes SO2 from the flue gas by using a buffer solution that can be regenerated. The buffer is then sent to a regenerative plant where the SO2 is extracted as concentrated SO2. The concentrated SO2 is then sent to a sulfur recovery unit (SRU) to recover the liquid SO2, sulfuric acid and elemental sulfur as a by-product. When the inlet SO2 concentrations are high, a substantial amount of sulfur-based by-products can be recovered and later sold as a commodity for use in the fertilizer, chemical, pulp and paper industries. For this reason, the use of regenerative wet gas scrubber is favored over non-regenerative wet gas scrubber.

One example of a regenerative scrubber is the proprietary LABSORB offered by BELCO Technologies Corporation. [5, 6] The LABSORB scrubbing process uses a patented non-organic aqueous solution of sodium phosphate salts as a buffer. This buffer is made from two common available products, caustic and phosphoric acid. The LABSORB scrubbing system is capable of reducing SOx to below 25 ppmv. The LABSORB system consists of: 1) a quench pre-scrubber; 2) an absorber; and, 3) a regeneration section which typically includes a stripper and a heat exchanger.

In the scrubbing side of the regenerative scrubbing system, the quench pre-scrubber is used to wash out any large particles that are carried over, plus any acid components in the flue gas such as hydrofluoric acid (HF), hydrochloric acid, and SO3. The absorption of SO2 is carried out in the absorber. The absorber typically consists of one single, high-efficiency packed bed scrubber filled with high-efficiency structural packing material. However, if the inlet SO2 concentration is low, a multiple-staged packed bed scrubber, or a spray-and-plate tower scrubber, may be used instead to achieve an outlet SO2 concentration of less than 25 ppmv.

The third step in the regenerative wet gas scrubbing system is the regenerative section in which the SO2-rich buffer stream is steam heated to evaporate the water from the buffer. The buffer stream is then sent to a stripper/condenser unit to separate the SO2 from the buffer. The buffer free of SO2 is returned to the buffer mixing tank while the condensed-SO2 gas stream is sent back to the SRU for further treatment.

Dry Gas Scrubbers

Dry gas scrubbers are used to control SOx emissions and can be installed to control emissions from cement kilns and coal-fired boilers, container glass melting furnaces, and refinery boilers and heaters. In dry gas scrubbers, a dry calcium- and sodium-based alkaline powdered sorbent is used to absorb SO2 from the flue (outlet) gas stream. There are two types of dry scrubbers: 1) spray dryer scrubbers; and, 2) dry injection scrubbers.

A spray dryer scrubber is configured so that the reaction between SO2 in the flue gas and the dry sorbent takes place in a separate, dedicated reactor (or scrubber). A dry injection scrubber is configured so that the sorbent is injected directly via multiple injection ports into the SO2-producing equipment or ducting system. Spray dryer scrubbers can achieve about 80 percent to 90 percent SO2 removal efficiency, while dry injection scrubbers can achieve about 50 percent to 80 percent SO2 removal efficiency.

Dry gas scrubbers require high temperatures in the range of 1,800 ^{o}F to 2,000 ^{o}F in order to decompose the sorbent into porous solids with high adsorbing surface area to ensure efficient SO2 removal. Because particulates are formed during the dry gas scrubbing process, cyclones and ESPs are additional control equipment units that are typically installed downstream of a dry scrubber.

SOx Reducing Additives

To help reduce condensable particulate matter from sulfur, SOx reducing catalysts are used for reducing the production of SOx by-products in FCCUs. SOx reducing catalyst is a metal oxide compound such as aluminum oxide (Al_2O_3), magnesium oxide (MgO), vanadium pentoxide (V_2O_5) or a combination of the three that is added to the FCCU catalyst as it circulates throughout the reactor. In the regenerator of the FCCU, sulfur bearing coke is burned and SO2, CO, and CO2 by-products are formed. A portion of SO2 will react with excess oxygen and form SO3 which will either stay in the flue gas or react with the metal oxide in the SOx reducing catalyst to form metal sulfate. In the FCCU reactor, the metal sulfate will react with hydrogen to form either metal sulfide and water, or more metal oxide. In the steam stripper section of the FCCU reactor, metal sulfide reacts with steam to form metal oxide and hydrogen sulfide. The net effect of these reactions is that the quantity of SOx in the regenerator is typically reduced between 40 to 65 percent while the quantity of hydrogen sulfide (H_2S) in the reactor is increased. Generally, the increase in H_2S is handled by sulfur recovery processes located elsewhere within the refinery.

Fuel Gas Treatment

Currently, SCAQMD Rule 431.1 – Sulfur Content of Gaseous Fuels, limits the sulfur content in refinery fuel gas to 40 ppmv sulfur. This limit has already been incorporated in the SOx RECLAIM allocations and resulted in an emission factor of 6.76 pounds of SOx per million cubic feet of refinery gas. However, the sulfur content in refinery fuel gas may be further reduced to a range between 25 ppmv and 35 ppmv and the outlet SOx concentrations from refinery boilers and process heaters may also be limited to less than 20 ppmv by implementing efficiency improvements to fuel gas treatment.

Refinery fuel gas, commonly used for operating refinery process heaters and boilers, is treated in various acid gas processing units such as an amine or Merox treating unit for removal of sour components such as hydrogen sulfide, carbonyl sulfide, mercaptan, and ammonia. Lean amine is generally used as an absorbent. At the end of the process, the lean amine is regenerated to form

rich amine, and H2S is recovered in acid gas which is then fed to the sulfur recovery unit/tail gas treatment unit for more processing. By improving the efficiency of the amine treating unit to recover more sulfur from the inlet acid gas stream, the sulfur content in the refinery fuel gas at the outlet, and subsequently the SOx emissions from boilers and heaters that use these refinery fuel gases can be reduced.

Selective Oxidation Catalyst

EmeraChem Power LLC markets a proprietary catalytic gas treatment called selective oxidation catalyst "ESx" that is typically used as a sulfur reducing agent in conjunction with its "EMx NOx trap" catalyst to treat combustion exhaust gases from incinerators, process heaters, turbines and boilers. The ESx catalyst can also be used as part of SOx reduction for sulfur recovery units/tail gas treatment units. The ESx catalyst can reduce multiple sulfur species, including SO2, SO3, and H2S from the tail gas stream while also removing CO, VOC, and PM10 emissions. ESx catalyst is a platinum group metal catalyst that stores sulfur species and simultaneously assists in the catalytic oxidation of CO and VOCs. The ESx units are typically outfitted with multiple chambers such that at least one chamber is always in regeneration while the other units are working to store SOx. In the storage process, SO2 is oxidized to SO3 and is stored by EmeraChem's sorber. The catalyst regeneration process releases sulfur as SO2.

ALTERNATIVES

The Draft EA will discuss and compare alternatives to the proposed project as required by CEQA and by SCAQMD Rule 110. Alternatives must include realistic measures for attaining the basic objectives of the proposed project and provide a means for evaluating the comparative merits of each alternative. In addition, the range of alternatives must be sufficient to permit a reasoned choice and it need not include every conceivable project alternative. The key issue is whether the selection and discussion of alternatives fosters informed decision making and public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative.

SCAQMD Rule 110 does not impose any greater requirements for a discussion of project alternatives in an environmental assessment than is required for an Environmental Impact Report under CEQA. Alternatives will be developed based in part on the major components of the proposed rule. The rationale for selecting alternatives rests on CEQA's requirement to present "realistic" alternatives; that is alternatives that can actually be implemented. CEQA also requires an evaluation of a "No Project Alternative."

SCAQMD's policy document Environmental Justice Program Enhancements for fiscal year (FY) 2002-03, Enhancement II-1 recommends that all SCAQMD CEQA assessments include a feasible project alternative with the lowest air toxics emissions. In other words, for any major equipment or process type under the scope of the proposed project that creates a significant environmental impact, at least one alternative, where feasible, shall be considered from a "least harmful" perspective with regard to hazardous air emissions.

The Governing Board may choose to adopt any portion or all of any alternative presented in the EA. The Governing Board is able to adopt any portion or all of any of the alternatives presented because the impacts of each alternative will be fully disclosed to the public and the public will have the opportunity to comment on the alternatives and impacts generated by each alternative.

Written suggestions on potential project alternatives received during the comment period for the Initial Study will be considered when preparing the Draft EA.

CHAPTER 2 - ENVIRONMENTAL CHECKLIST

Introduction

General Information

Potentially Significant Impact Areas

Determination

Environmental Checklist and Discussion

INTRODUCTION

The environmental checklist provides a standard evaluation tool to identify a project's adverse environmental impacts. This checklist identifies and evaluates potential adverse environmental impacts that may be created by adopting the proposed amendments to Regulation XX.

GENERAL INFORMATION

Project Title:	Proposed Amended Regulation XX – Regional Clean Air Incentives Market (RECLAIM)
Lead Agency Name:	South Coast Air Quality Management District
Lead Agency Address:	21865 Copley Drive, Diamond Bar, CA 91765
CEQA Contact Person:	Barbara Radlein, (909) 396-2716
Rule Contact Person:	Minh Pham, (909) 396-2613
Project Sponsor's Name:	South Coast Air Quality Management District
Project Sponsor's Address:	21865 Copley Drive, Diamond Bar, CA 91765
General Plan Designation:	Not applicable
Zoning:	Not applicable
Description of Project:	SCAQMD staff is proposing amendments to Regulation XX – Regional Clean Air Incentives Market (RECLAIM), Rule 2002 – Allocations for Oxides of Nitrogen (NOx) and Oxides of Sulfur (SOx), to reduce the allowable SOx emission limits based on current Best Available Retrofit Control Technology (BARCT) for the following industrial equipment and processes: 1) fluid catalytic cracking units (FCCUs); 2) refinery boilers and heaters; 3) sulfur recovery – tail gas treatment units; 4) sulfuric acid manufacturing process; 5) container glass manufacturing process; 6) coke calcining; and, 7) portland cement manufacturing. Additional amendments are proposed to establish procedures and criteria for reducing RECLAIM Trading Credits (RTCs) and RTC adjustment factors for year 2013 and later. Other minor changes are proposed for clarity and consistency throughout the regulation. The Initial Study identifies the topics of aesthetics, air quality, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic as areas that may be adversely affected by the proposed project. Impacts to these environmental areas will be further analyzed in the Draft EA.
Surrounding Land Uses and Setting:	Residential, but primarily commercial, industrial and/or institutional
Other Public Agencies Whose Approval is Required:	Not applicable

POTENTIALLY SIGNIFICANT IMPACT AREAS

The following environmental impact areas have been assessed to determine their potential to be affected by the proposed project. Any checked items represent areas that may be adversely affected by the proposed project. An explanation relative to the determination of impacts can be found following the checklist for each area.

☑	Aesthetics	☐	Geology and Soils	☐	Population and Housing
☐	Agricultural Resources	☑	Hazards and Hazardous Materials	☐	Public Services
☑	Air Quality	☑	Hydrology and Water Quality	☐	Recreation
☐	Biological Resources	☐	Land Use and Planning	☐	Solid/Hazardous Waste
☐	Cultural Resources	☐	Mineral Resources	☑	Transportation/Traffic
☑	Energy	☐	Noise	☑	Mandatory Findings

DETERMINATION
On the basis of this initial evaluation:

☐ I find the proposed project, in accordance with those findings made pursuant to CEQA Guideline §15252, COULD NOT have a significant effect on the environment, and that an ENVIRONMENTAL ASSESSMENT with no significant impacts has been prepared.

☐ I find that although the proposed project could have a significant effect on the environment, there will NOT be significant effects in this case because revisions in the project have been made by or agreed to by the project proponent. An ENVIRONMENTAL ASSESSMENT with no significant impacts will be prepared.

☑ I find that the proposed project MAY have a significant effect(s) on the environment, and an ENVIRONMENTAL ASSESSMENT will be prepared.

☐ I find that the proposed project MAY have a "potentially significant impact" on the environment, but at least one effect 1)has been adequately analyzed in an earlier document pursuant to applicable legal standards, and 2) has been addressed by mitigation measures based on the earlier analysis as described on attached sheets. An ENVIRONMENTAL ASSESSMENT is required, but it must analyze only the effects that remain to be addressed.

☐ I find that although the proposed project could have a significant effect on the environment, because all potentially significant effects (a) have been analyzed adequately in an earlier ENVIRONMENTAL ASSESSMENT pursuant to applicable standards, and (b) have been avoided or mitigated pursuant to that earlier ENVIRONMENTAL ASSESSMENT, including revisions or mitigation measures that are imposed upon the proposed project, nothing further is required.

Planning, Rules, and Area Sources

ENVIRONMENTAL CHECKLIST AND DISCUSSION

Since SOx is a precursor pollutant to fine particulate matter as PM10 and PM2.5, SCAQMD staff is proposing amendments to Regulation XX – RECLAIM to achieve additional SOx emission reductions as outlined in the 2007 AQMP. Specifically, amendments are proposed to SCAQMD Rule 2002, to address BARCT requirements, which may require installation or modification of SOx emission control equipment. Other changes proposed are administrative in nature and include minor clarifications for continuity.

The amendments proposed in Rule 2002 for the overall reductions in SOx RTC allocations, which include the anticipated feasible SOx emissions reductions due to compliance with proposed BARCT requirements, are expected to involve physical changes at affected facilities which may cause potentially significant impacts to the following environmental topics: aesthetics, air quality, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic. Therefore, the type of emission reduction projects that may be undertaken to comply with the proposed project, primarily the reduced total amounts of SOx credits available in the RECLAIM program, are the main focus of the analysis in this Initial Study.

Preliminary review of the SCAQMD's RECLAIM database indicates that certain equipment at 12 SOx RECLAIM facilities are currently not operating at proposed BARCT levels. This analysis assumes that operators at RECLAIM facilities will elect to reduce emissions at their facilities through further control of emissions from equipment not operating at BARCT rather than purchasing SOx RTCs, as is currently allowed under the RECLAIM program. The rationale for this assumption is that controlling emissions from equipment not operating at BARCT will be the most cost effective approach and produces the most conservative analysis of secondary adverse environmental impacts.

The physical changes involved with the type of emission control strategies that are expected to occur focus on the installation of new or the modification of existing control equipment at the following stationary sources of SOx: petroleum coke calciners, cement kilns, coal-fired boiler, container glass melting furnaces, diesel combustion of liquid fuels, FCCUs, refinery boilers and process heaters, sulfur recovery units/tail gas treatment units, and sulfuric acid manufacturing facilities. To control SOx emissions from these sources, the following technologies are proposed as BARCT: wet gas scrubbers, dry gas scrubbers, hybrid dry gas scrubber (dry gas scrubber plus a baghouse), SOx reducing catalysts, fuel gas treatment, and selective oxidation catalyst treatment.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
I.	**AESTHETICS.** Would the project:			
a)	Have a substantial adverse effect on a scenic vista?	☐	☐	☑
b)	Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?	☐	☐	☑
c)	Substantially degrade the existing visual character or quality of the site and its surroundings?	☑	☐	☐
d)	Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?	☐	☑	☐

Significance Criteria

The proposed project impacts on aesthetics will be considered significant if:

- The project will block views from a scenic highway or corridor.
- The project will adversely affect the visual continuity of the surrounding area.
- The impacts on light and glare will be considered significant if the project adds lighting which would add glare to residential areas or sensitive receptors.

Discussion

I. a), & b) Implementation of the proposed project is expected to involve construction activities related to the modification of existing equipment at the top 12 SOx emitting RECLAIM facilities. The distribution of these SOx RECLAIM facilities is as follows: six are oil refineries, two are sulfuric acid manufacturing plants, one is a coke calciner plant, one is a cement manufacturing plant, and two are container glass manufacturing plants.

The physical changes involved with the type of SOx emission control strategies that are expected focus on the installation of new or the modification of existing control equipment at the following stationary sources of SOx: petroleum coke calciners, cement kilns, coal-fired boiler, container glass melting furnaces, diesel combustion of liquid fuels, FCCUs, refinery boilers and process heaters, sulfur recovery units/tail gas treatment units, and sulfuric acid manufacturing facilities. To control SOx emissions from these sources, the following technologies are proposed as BARCT: wet gas scrubbers, dry gas scrubbers, hybrid dry gas scrubber (dry gas scrubber plus a baghouse), SOx reducing catalysts, fuel gas treatment, and selective oxidation catalyst treatment.

Construction activities are expected as part of the proposed project. However, the construction activities are not expected to adversely impact views and aesthetics resources since most of the heavy equipment and activities are expected to occur within the confines of each existing facility and are expected to introduce only minor visual changes to areas outside each facility, if at all, depending on the location of the construction activities within the facility. Except for the use of cranes, the majority of the construction equipment is expected to be low in height and not

substantially visible to the surrounding area due to existing fencing along the property lines and existing structures currently within the facilities that would buffer the views of the construction activities. Further, the construction activities are expected to be temporary in nature and will cease following completion of the equipment installation or modifications.

Depending on the type of SOx emissions control employed, the proposed project could potentially introduce minor visual changes at some facilities. The affected units, depending upon their locations within each facility, could potentially be visible to areas outside of each facility. However, the affected units are expected to be about the same size profile as existing equipment present at each affected facility. The general appearance of the affected units is not expected to differ significantly from other equipment units such that no significant impacts to aesthetics are expected. Further, no scenic highways or corridors are located in the vicinities of the affected facilities such that the proposed project would not obstruct scenic resources or degrade the existing visual character of a site, including but not limited to, trees, rock outcroppings, or historic buildings.

I. c) All construction and operational activities associated with the proposed project are expected to take place within the boundaries of the existing RECLAIM facilities. The new equipment to be installed, or the existing equipment to be modified as part of the proposed project, will be similar in size, appearance, and profile to the existing equipment, with the exception of any installation of a wet gas scrubber

Except for the use of cranes, the majority of construction equipment that will be used to comply with the proposed project will be low in height and will not be visible to the surrounding areas due to the presence of existing fences and other structures that buffer views. During construction, cranes may be visible to the surrounding areas. Since the construction activities are temporary in nature, all construction equipment will be removed following completion of the proposed project.

Wet gas scrubber technology is potentially BARCT for six oil refineries (for six FCCUs and six sulfur recovery units/tail gas treatment units), two sulfuric acid manufacturing plants, one coke calciner plant, one cement manufacturing plant, and two container glass manufacturing plants. Upon completion of construction of all of these wet gas scrubbers, the operational activities of these units will emit flue gas that is saturated with water, forming a visible steam plume from a relatively high flue gas stack (approximately 200 feet above grade). Each stack and subsequent plume will have the potential to generate significant aesthetic impacts. Therefore, these potential impacts to aesthetics will be addressed in the Draft Environmental Assessment (EA) for the proposed project.

I. d) There are no components in the proposed project that would require construction activities to occur at night. Therefore, no additional lighting at the affected facilities would be required as a result of complying with the proposed project. However, if facility operators determine that the construction schedule requires nighttime activities, temporary lighting may be required. Nonetheless, since construction of the proposed project would be completely located within the boundaries of each affected facility, additional temporary lighting is not expected to be discernable from the existing permanent night lighting.

Additional permanent light sources may be installed on any installation of new equipment, to provide illumination for operations personnel at night, in accordance with applicable safety standards. Similarly, any existing equipment that would be modified as part of the proposed project are located in existing structures or areas that already have lighting systems in place for the same reasons. These additional light sources are not expected to create an impact because each component of the proposed project will be located within an existing industrial facility that operates up to 24 hours per day and the equipment is not restricted to operate during a specific time of day. The proposed project contains no provisions that would require affected equipment to operate differently during existing daytime or nighttime operations. Further, any new lighting that will be installed on the proposed equipment will be consistent in intensity and type with the existing lighting on equipment and other structures within each affected facility. While residential areas are located near some of the affected facilities, any additional lighting will be placed by and focused on the new equipment. For the aforementioned reasons, the proposed project is not expected to create a new source of substantial light or glare that would adversely affect day or nighttime views in the area. Therefore, less than significant impacts to light and glare are expected from the proposed project.

Based upon these considerations, significant adverse impacts to aesthetics are expected from the implementation of the proposed project and will be further analyzed in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
II.	**AGRICULTURE RESOURCES.** Would the project:			
a)	Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland mapping and Monitoring Program of the California Resources Agency, to non-agricultural use?	☐	☐	☑
b)	Conflict with existing zoning for agricultural use, or a Williamson Act contract?	☐	☐	☑
c)	Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use?	☐	☐	☑

Significance Criteria

Project-related impacts on agricultural resources will be considered significant if any of the following conditions are met:

- The proposed project conflicts with existing zoning or agricultural use or Williamson Act contracts.

- The proposed project will convert prime farmland, unique farmland or farmland of statewide importance as shown on the maps prepared pursuant to the farmland mapping and monitoring program of the California Resources Agency, to non-agricultural use.
- The proposed project would involve changes in the existing environment, which due to their location or nature, could result in conversion of farmland to non-agricultural uses.

Discussion

II. a), b), & c) All construction and operational activities that would occur as a result of implementing the proposed project are expected to occur within the confines of the existing affected facilities. The proposed project would be consistent with the commercial, industrial and institutional zoning requirements for the various facilities and there are no agricultural resources or operations on or near the affected facilities. No agricultural resources including Williamson Act contracts are located within or would be impacted by construction activities at the affected facilities. Therefore, the proposed project would not result in any new construction of buildings or other structures that would convert farmland to non-agricultural use or conflict with zoning for agricultural use or a Williamson Act contract. Since the proposed project would not substantially change the facility or process for which the affected units are utilized, there are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments and no land use or planning requirements relative to agricultural resources will be altered by the proposed project

Based upon these considerations, significant agricultural resource impacts are not expected from the implementation of the proposed project and will not be further analyzed in the Draft EA.

	Potentially Significant Impact	**Less Than Significant Impact**	**No Impact**
III. AIR QUALITY. Would the project:			
a) Conflict with or obstruct implementation of the applicable air quality plan?	☐	☐	☑
b) Violate any air quality standard or contribute to an existing or projected air quality violation?	☑	☐	☐
c) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors)?	☑	☐	☐
d) Expose sensitive receptors to substantial pollutant concentrations?	☑	☐	☐

	Potentially Significant Impact	Less Than Significant Impact	No Impact
e) Create objectionable odors affecting a substantial number of people?	☐	☑	☐
f) Diminish an existing air quality rule or future compliance requirement resulting in a significant increase in air pollutant(s)?	☐	☐	☑

Significance Criteria
To determine whether or not air quality impacts from the proposed project may be significant, impacts will be evaluated and compared to the criteria in Table 2-1. If impacts exceed any of the criteria in Table 2-1, they will be considered further in the Draft EA. As necessary, all feasible mitigation measures will be identified in the Draft EA and implemented to reduce significant impacts to the maximum extent feasible.

Discussion
Upon initial examination of the proposed project, the main focus of this analysis pertains to establishing BARCT for the following top 12 stationary sources in the SOx RECLAIM program: petroleum coke calciners, cement kilns, coal-fired boiler, container glass melting furnaces, diesel combustion of liquid fuels, FCCUs, refinery boilers and process heaters, sulfur recovery units/tail gas treatment units, and sulfuric acid manufacturing facilities. To control SOx emissions from these sources, the following technologies are proposed as BARCT: wet gas scrubbers, dry gas scrubbers, hybrid dry gas scrubber (dry gas scrubber plus a baghouse), SOx reducing catalysts, fuel gas treatment, and selective oxidation catalyst treatment. The physical changes involved with the type of SOx emission control strategies that are expected to occur focus on the installation of new or the modification of existing control equipment. The possibility of these types of SOx control technologies being used to comply with the proposed project and potential secondary adverse air quality impacts they may generate will be further evaluated in the Draft EA. The remaining portions of the proposed project are procedural in nature and will not result in an adverse air quality impact.

III. a) The SCAQMD is required by law to prepare a comprehensive district-wide AQMP which includes strategies (e.g., control measures) to reduce emission levels to achieve and maintain state and federal ambient air quality standards, and to ensure that new sources of emissions are planned and operated to be consistent with the SCAQMD's air quality goals. The AQMP's air pollution reduction strategies include control measures which target stationary, mobile and indirect sources. These control measures are based on feasible methods of attaining ambient air quality standards. Pursuant to the provisions of both the state and federal Clean Air Acts, the SCAQMD is required to attain the state and federal ambient air quality standards for all criteria pollutants, including PM10 and PM2.5. Although the District is currently classified as attainment for both state and federal SO2 ambient air quality standards, SOx is a precursor pollutant to PM10 and PM2.5. The proposed project implements AQMP Control Measure CM #2007CMB-02 which will bring the SOx RECLAIM program up-to-date with the latest BARCT

Table 2-1
SCAQMD Air Quality Significance Thresholds

Mass Daily Thresholds [a]		
Pollutant	**Construction [b]**	Operation [c]
NOx	100 lbs/day	55 lbs/day
VOC	75 lbs/day	55 lbs/day
PM10	150 lbs/day	150 lbs/day
PM2.5	55 lbs/day	55 lbs/day
SOx	150 lbs/day	150 lbs/day
CO	550 lbs/day	550 lbs/day
Lead	3 lbs/day	3 lbs/day
Toxic Air Contaminants (TACs) and Odor Thresholds		
TACs (including carcinogens and non-carcinogens)	Maximum Incremental Cancer Risk ≥ 10 in 1 million Hazard Index ≥ 1.0 (project increment)	
Odor	Project creates an odor nuisance pursuant to SCAQMD Rule 402	
Ambient Air Quality for Criteria Pollutants [d]		
NO2 1-hour average annual average	SCAQMD is in attainment; project is significant if it causes or contributes to an exceedance of the following attainment standards: 0.25 ppm (state) 0.053 ppm (federal)	
PM10 24-hour average annual geometric average annual arithmetic mean	10.4 μg/m^3 (construction)[e] & 2.5 μg/m^3 (operation) 1.0 μg/m^3 20 μg/m^3	
PM2.5 24-hour average	10.4 μg/m^3 (construction)[e] & 2.5 μg/m^3 (operation)	
Sulfate 24-hour average	1 μg/m^3	
CO 1-hour average 8-hour average	SCAQMD is in attainment; project is significant if it causes or contributes to an exceedance of the following attainment standards: 20 ppm (state) 9.0 ppm (state/federal)	

[a] Source: SCAQMD CEQA Handbook (SCAQMD, 1993)
[b] Construction thresholds apply to both the South Coast Air Basin and Coachella Valley (Salton Sea and Mojave Desert Air Basins).
[c] For Coachella Valley, the mass daily thresholds for operation are the same as the construction thresholds.
[d] Ambient air quality thresholds for criteria pollutants based on SCAQMD Rule 1303, Table A-2 unless otherwise stated.
[e] Ambient air quality threshold based on SCAQMD Rule 403.

KEY: lbs/day = pounds per day; ppm = parts per million; μg/m^3 = microgram per cubic meter; ≥ greater than or equal to

requirements to achieve, at a minimum, the proposed SOx emission reductions in CM #2007CMB-02 (at least 2.9 tons per day by compliance year 2014). Therefore, the proposed project will not obstruct or conflict with the implementation of the AQMP.

Although the proposed project has the potential to temporarily increase VOC, NOx, CO, PM10 and TAC emissions (as diesel PM) that could exceed the air quality significance thresholds for construction activities, the proposed project is not expected to interfere with achieving at least 2.9 tons per day of SOx emission reductions by the year 2014, which is consistent with the goals of the 2007 AQMP to achieve additional SOx emission reductions (and reduce SOx precursors as PM 2.5 and PM10) from stationary sources, which will assist in attaining state and federal PM2.5 and PM10 ambient air quality standards. Further, the temporary increase in VOC, NOx, CO, PM10 and TAC emissions (as diesel PM) due to construction is not expected to impede the emission reduction goals of the 2007 AQMP because the inventory prepared for the 2007 AQMP already takes into account the future emission estimates from all construction activities associated with implementing the proposed control measures[7]. Further, implementation of all other SCAQMD SOx rules along with AQMP control measures, when considered together, is expected to reduce SOx emissions throughout the region overall by 2020. Therefore, implementing the proposed project will not conflict or obstruct implementation of the AQMP.

III. b) The objective of the proposed project is to reduce SOx emissions from the following top 12 stationary sources in the SOx RECLAIM program: petroleum coke calciners, cement kilns, coal-fired boiler, container glass melting furnaces, diesel combustion of liquid fuels, FCCUs, refinery boilers and process heaters, sulfur recovery units/tail gas treatment units, and sulfuric acid manufacturing facilities. The proposed project is estimated to reduce emissions, at a minimum, of up to 2.9 tons per day of SOx by 2014 from these affected units. Compliance with the proposed project is expected to be achieved by the following SOx control technologies: wet gas scrubbers, dry gas scrubbers, hybrid dry gas scrubber (dry gas scrubber plus a baghouse), SOx reducing catalysts, fuel gas treatment, and selective oxidation catalyst treatment.

Implementation of the proposed project is expected to involve construction activities related to the installation or modification of the aforementioned SOx control technologies at 12 industrial facilities. The proposed project may also involve the construction of new buildings or other structures as part of installation or modification of the SOx controls. Construction-related activities are also expected to generate emissions from worker vehicles, trucks, and construction equipment. Due to the large scale of construction that would be expected from implementing the proposed project, project-specific construction emissions are potentially significant.

While the operational-related activities are expected to reduce emissions of SOx, a simultaneous increase in emissions of other criteria pollutants such as NOx and VOCs are expected from operations of stationary support equipment associated with the installed or modified SOx control equipment, as well as operational emissions associated with periodic truck deliveries of supplies needed to operate the SOx control equipment. Thus, the air quality impacts associated with the construction and operational phases of the proposed project are potentially significant and will be evaluated in the Draft EA.

[7] SCAQMD's Final Program Environmental Impact Report for the 2007 Air Quality Management Plan, SCH#2006111064, June 2007.

III. c) The anticipated SOx emission reductions that would result from implementing the proposed project are expected to improve the overall air quality in the Basin by enhancing the probability of attaining and maintaining state and federal ambient air quality standards for PM10 and PM2.5. However, the secondary construction and operation impacts associated with reducing SOx have the potential for creating significant adverse cumulative air quality impacts that will be evaluated in the Draft EA. In addition, operational activities associated with the proposed project also have the potential to increase emissions of greenhouse gases (GHGs); these potential increases will be evaluated in the Draft EA as part of the cumulative impacts discussion.

III. d) Emission sources associated with the construction-related activities as a result of implementing the proposed project may temporarily emit toxic air contaminants (TACs). Further, emissions sources associated with the operational-related activities as a result of implementing the proposed project may emit TACs. The impact of these emissions on sensitive populations, including individuals at hospitals, nursing facilities, daycare centers, schools, and elderly intensive care facilities, as well as residential and off-site occupational areas, will be evaluated in the Draft EA.

III. e) The proposed project is not expected to create significant adverse objectionable odors, either during construction or during operations. Sulfur compounds such as hydrogen sulfide, sulfur dioxide, sulfur trioxide, and sulfuric acid are the primary sources of odors from existing operations throughout the 12 affected SOx RECLAIM facilities. However, the objective of the proposed project is to implement BARCT which is expected to result in the installation of SOx controls and the reduction of sulfur-laden compounds that could otherwise generate odors. In other words, the proposed project is expected to reduce odor generation potential, a beneficial result of implementing the proposed project. Therefore, no significant odor impacts are expected from the proposed project.

III. f) The proposed project will be required to comply with all applicable SCAQMD, CARB, and EPA rules and regulations. Thus, the proposed project is not expected to diminish an existing air quality rule or future compliance requirements. Further, adopting and implementing the proposed project enhances existing air pollution control rules that are expected to assist the SCAQMD in its efforts to attain and maintain with a margin of safety the state and federal ambient air quality standards for PM10 and PM2.5.

Based upon these considerations, the air quality impacts associated with increased emissions of criteria air contaminants and GHGs during the construction phase and the increased emissions of GHGs during the operation phase of the proposed project will be evaluated further in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
IV. BIOLOGICAL RESOURCES. Would the project:			
a) Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☐	☐	☑
b) Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☐	☐	☑
c) Have a substantial adverse effect on federally protected wetlands as defined by §404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?	☐	☐	☑
d) Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?	☐	☐	☑
e) Conflicting with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?	☐	☐	☑
f) Conflict with the provisions of an adopted Habitat Conservation plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?	☐	☐	☑

Significance Criteria

Impacts on biological resources will be considered significant if any of the following criteria apply:

- The project results in a loss of plant communities or animal habitat considered to be rare, threatened or endangered by federal, state or local agencies.
- The project interferes substantially with the movement of any resident or migratory wildlife species.
- The project adversely affects aquatic communities through construction or operation of the project.

Discussion

IV. a), b), c), & d) The proposed project would only affect units operating at 12 existing facilities located throughout the district. All of the affected units operating at existing facilities are located primarily in industrial areas, which have already been greatly disturbed. These areas currently do not support riparian habitat, federally protected wetlands, or migratory corridors. Additionally, special status plants, animals, or natural communities are not expected to be found within close proximity to the affected facilities. Therefore, the proposed project would have no direct or indirect impacts that could adversely affect plant or animal species or the habitats on which they rely in the SCAQMD's jurisdiction. The current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions. A conclusion in the Program Environmental Impact Report (EIR) for the 2007 AQMP was that population growth in the region would have greater adverse effects on plant species and wildlife dispersal or migration corridors in the basin than SCAQMD regulatory activities, (e.g., air quality control measures or regulations). The current and expected future land use development to accommodate population growth is primarily due to economic considerations or local government planning decisions.

IV. e) & f) The proposed project is not envisioned to conflict with local policies or ordinances protecting biological resources or local, regional, or state conservation plans. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Additionally, the proposed project will not conflict with any adopted Habitat Conservation Plan, Natural Community Conservation Plan, or any other relevant habitat conservation plan, and would not create divisions in any existing communities because all activities associated with complying with the proposed project will occur at existing industrial facilities.

Based upon these considerations, significant biological resource impacts are not expected from the implementation of the proposed project and will not be further analyzed in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
V.	**CULTURAL RESOURCES.** Would the project:			
a)	Cause a substantial adverse change in the significance of a historical resource as defined in §15064.5?	☐	☐	☑
b)	Cause a substantial adverse change in the significance of an archaeological resource as defined in §15064.5?	☐	☐	☑
c)	Directly or indirectly destroy a unique paleontological resource, site, or feature?	☐	☐	☑
d)	Disturb any human remains, including those interred outside a formal cemeteries?	☐	☐	☑

Significance Criteria
Impacts to cultural resources will be considered significant if:
- The project results in the disturbance of a significant prehistoric or historic archaeological site or a property of historic or cultural significance to a community or ethnic or social group.
- Unique paleontological resources are present that could be disturbed by construction of the proposed project.
- The project would disturb human remains.

Discussion
V. a) There are existing laws in place that are designed to protect and mitigate potential impacts to cultural resources. Since construction-related activities associated with the implementation of the proposed project are expected to be confined within the existing footprint of the 12 affected facilities, no impacts to historical resources are expected to occur as a result of implementing the proposed project.

V. b), c), & d) Installing or modifying add-on controls and other associated equipment to comply with the proposed project will require disturbance of previously disturbed areas at 12 existing industrial facilities. However, since construction-related activities are expected to be confined within the existing footprint of these affected facilities, the proposed project is not expected to require physical changes to the environment, which may disturb paleontological or archaeological resources. Furthermore, it is envisioned that these areas are already either devoid of significant cultural resources or whose cultural resources have been previously disturbed. Therefore, the proposed project has no potential to cause a substantial adverse change to a historical or archaeological resource, directly or indirectly destroy a unique paleontological resource or site or unique geologic feature, or disturb any human remains, including those interred outside a formal cemeteries. The proposed project is, therefore, not anticipated to result in any activities or promote any programs that could have a significant adverse impact on cultural resources in the district.

Based upon these considerations, significant cultural resources impacts are not expected from the implementation of the proposed project and will not be further analyzed in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
VI.	**ENERGY.** Would the project:			
a)	Conflict with adopted energy conservation plans?	☐	☐	☑
b)	Result in the need for new or substantially altered power or natural gas utility systems?	☑	☐	☐
c)	Create any significant effects on local or regional energy supplies and on requirements for additional energy?	☑	☐	☐

		Potentially Significant Impact	Less Than Significant Impact	No Impact
d)	Create any significant effects on peak and base period demands for electricity and other forms of energy?	☑	☐	☐
e)	Comply with existing energy standards?	☐	☐	☑

Significance Criteria

Impacts to energy and mineral resources will be considered significant if any of the following criteria are met:

- The project conflicts with adopted energy conservation plans or standards.
- The project results in substantial depletion of existing energy resource supplies.
- An increase in demand for utilities impacts the current capacities of the electric and natural gas utilities.
- The project uses non-renewable resources in a wasteful and/or inefficient manner.

Discussion

The proposed project would reduce emissions of SOx from various stationary sources at 12 affected facilities. The expected options for compliance are either installing or modifying air pollution control equipment appropriate to the type of process unit. Further, it is expected that the installation and operation of any equipment used to comply with the proposed project will also comply with all applicable existing energy standards.

VI. a) & e) The proposed project is not subject to any existing energy conservation plans. If a facility that is subject to Regulation XX and the proposed project is also subject to energy conservation plans, it is not expected that the proposed project will affect in any way or interfere with that facility's ability to comply with its energy conservation plan or energy standards. Further, project construction and operation activities will not utilize non-renewable energy resources in a wasteful or inefficient manner.

VI. b), c) & d. Installation or modification of air pollution control equipment to comply with the proposed project is expected to increase demand for energy used for operating the primary equipment as well as support equipment such as pumps, fans, controllers, et cetera.

Any additional electricity required is typically either supplied by each affected facility's cogeneration units, for those that have them, or by the local electrical utility, as appropriate. It is possible that some facilities may need new or substantially altered power utility systems to be built to accommodate any additional electricity demands created by the proposed project. In some cases, an increase in natural gas use is also expected for operations subject to the proposed project.

Based upon these considerations, significant adverse impacts to energy are expected from implementation of the proposed project and will be evaluated further in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
VII.	**GEOLOGY AND SOILS.** Would the project:			
a)	Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:			
	• Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault?	☐	☐	☑
	• Strong seismic ground shaking?	☐	☐	☑
	• Seismic–related ground failure, including liquefaction?	☐	☐	☑
	• Landslides?	☐	☐	☑
b)	Result in substantial soil erosion or the loss of topsoil?	☐	☐	☑
c)	Be located on a geologic unit or soil that is unstable or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse?	☐	☐	☑
d)	Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?	☐	☐	☑
e)	Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?	☐	☐	☑

Significance Criteria

Impacts on the geological environment will be considered significant if any of the following criteria apply:

- Topographic alterations would result in significant changes, disruptions, displacement, excavation, compaction or over covering of large amounts of soil.
- Unique geological resources (paleontological resources or unique outcrops) are present that could be disturbed by the construction of the proposed project.
- Exposure of people or structures to major geologic hazards such as earthquake surface rupture, ground shaking, liquefaction or landslides.
- Secondary seismic effects could occur which could damage facility structures, e.g., liquefaction.

- Other geological hazards exist which could adversely affect the facility, e.g., landslides, mudslides.

Discussion

VII. a) Since the proposed project would result in construction activities at 12 industrial settings to install or modify SOx control equipment, little site preparation is anticipated that could adversely affect geophysical conditions in the jurisdiction of the SCAQMD. Southern California is an area of known seismic activity. Accordingly, the installation of add-on controls at existing affected facilities to comply with the proposed project is expected to conform to the Uniform Building Code and all other applicable state and local building codes. As part of the issuance of building permits, local jurisdictions are responsible for assuring that the Uniform Building Code is adhered to and can conduct inspections to ensure compliance. The Uniform Building Code is considered to be a standard safeguard against major structural failures and loss of life. The basic formulas used for the Uniform Building Code seismic design require determination of the seismic zone and site coefficient, which represents the foundation condition at the site. The Uniform Building Code requirements also consider liquefaction potential and establish stringent requirements for building foundations in areas potentially subject to liquefaction. Thus, the proposed project would not alter the exposure of people or property to geological hazards such as earthquakes, landslides, mudslides, ground failure, or other natural hazards. As a result, substantial exposure of people or structures to the risk of loss, injury, or death involving the rupture of an earthquake fault, seismic ground shaking, ground failure or landslides is not anticipated and will not be further analyzed in the Draft EA.

VII. b) Since add-on controls will likely be installed at existing facilities, during construction of the proposed project, a slight possibility exists for temporary erosion resulting from excavating and grading activities, if required. These activities are expected to be minor since the existing facilities are generally flat and have previously been graded. Further, wind erosion is not expected to occur to any appreciable extent, because operators at dust generating sites would be required to comply with the best available control measure (BACM) requirements of SCAQMD Rule 403 – Fugitive Dust. In general, operators must control fugitive dust through a number of soil stabilizing measures such as watering the site, using chemical soil stabilizers, revegetating inactive sites, etc. The proposed project involves the installation or modification of add-on control equipment at 12 existing facilities, so that grading could be required to provide stable foundations. Potential air quality impacts related to grading are addressed elsewhere in this Initial Study (as part of construction air quality impacts). No unstable earth conditions or changes in geologic substructures are expected to result from implementing the proposed project.

VII. c) Since the proposed project will affect existing facilities, it is expected that the soil types present at the affected facilities will not be further susceptible to expansion or liquefaction. Furthermore, subsidence is not anticipated to be a problem since only minor excavation, grading, or filling activities are expected occur at affected facilities. Additionally, the affected areas are not envisioned to be prone to new landslide impacts or have unique geologic features since the affected equipment units are located at existing facilities in industrial areas.

VII. d) & e) Since the proposed project will affect equipment units at existing facilities located in industrial zones, it is expected that people or property will not be exposed to new impacts related to expansive soils or soils incapable of supporting water disposal. Further, typically each affected facility has some degree of existing wastewater treatment systems that will continue to

be used and are expected to be unaffected by the proposed project. Sewer systems are available to handle wastewater produced and treated by each affected facility. Each existing facility affected by the proposed project does not require installation of septic tanks or alternative wastewater disposal systems. As a result, the proposed project will not require facility operators to utilize septic systems or alternative wastewater disposal systems. Thus, implementation of the proposed project will not adversely affect soils associated with a septic system or alternative wastewater disposal system.

Based upon these considerations, significant geology and soils impacts are not expected from the implementation of the proposed project and will not be further analyzed in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
VIII.	**HAZARDS AND HAZARDOUS MATERIALS.** Would the project:			
a)	Create a significant hazard to the public or the environment through the routine transport, use, and disposal of hazardous materials?	☑	☐	☐
b)	Create a significant hazard to the public or the environment through reasonably foreseeable upset conditions involving the release of hazardous materials into the environment?	☑	☐	☐
c)	Emit hazardous emissions, or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?	☑	☐	☐
d)	Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code §65962.5 and, as a result, would create a significant hazard to the public or the environment?	☑	☐	☐
e)	For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?	☐	☑	☐
f)	For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?	☐	☑	☐
g)	Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	☐	☐	☑

		Potentially Significant Impact	Less Than Significant Impact	No Impact
h)	Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?	☐	☐	☑
i)	Significantly increased fire hazard in areas with flammable materials?	☐	☐	☑

Significance Criteria

Impacts associated with hazards will be considered significant if any of the following occur:

- Non-compliance with any applicable design code or regulation.
- Non-conformance to National Fire Protection Association standards.
- Non-conformance to regulations or generally accepted industry practices related to operating policy and procedures concerning the design, construction, security, leak detection, spill containment or fire protection.
- Exposure to hazardous chemicals in concentrations equal to or greater than the Emergency Response Planning Guideline (ERPG) 2 levels.

Discussion

VIII. a) & b) New or modified air pollution control equipment and related components are expected to be installed at most of the 12 affected facilities such that their operations may increase the quantity of hazardous materials (e.g., catalysts, scrubbing agents) used by the control equipment. In addition, the shipping, handling, storing, and disposing of hazardous materials inherently poses a certain risk of a release to the environment. Thus, the routine transport of hazardous materials, use, and disposal of hazardous materials may increase as a result of implementing the proposed project. Further, if the control option chosen by each affected facility operator is a wet gas scrubber, the proposed project may alter the transportation modes for catalyst and scrubbing agent feedstock and any other associated chemicals to/from the existing facilities.

For these reasons, implementation of the proposed project may alter the hazards associated with the existing affected facilities. At many of the affected facilities, a number of hazardous materials are currently in use. In general, the major types of public safety risks that need to be evaluated consist of impacts resulting from toxic substance releases, fires, and explosions.

Therefore, potential hazards impacts as a result of implementing the proposed project are potentially significant and will be addressed in the Draft EA.

VIII. c) Some affected facilities may be located within one-quarter mile of a sensitive receptor (e.g., a day care center). Therefore, a potential for significant impacts from hazardous emissions or the handling of acutely hazardous materials, substances and wastes near sensitive-receptors may occur and will be addressed in the Draft EA.

VIII. d) Government Code §65962.5 refers to hazardous waste handling practices at facilities subject to the Resources Conservation and Recovery Act (RCRA). Construction activities associated with implementing the proposed project will occur within the confines of the existing affected facilities. Some of the affected facilities may be included on the list of the hazardous materials sites compiled pursuant to Government Code §65962.5. Hazardous wastes from these existing facilities are managed in accordance with applicable federal, state, and local rules and regulations. The types of additional waste expected to be generated from implementing the proposed project will consist primarily of additional catalyst used by the new SOx control devices. For those affected facilities which already use catalyst for other operational activities on-site, the additional collected spent catalyst will continue to be handled in the same manner as currently handled such that it will be disposed and/or recycled at approved facilities. Further, if any of other affected facilities are new to handling catalyst waste, the same disposal/recycling procedures are expected to be followed. Accordingly, significant hazards impacts from the disposal and/or recycling of hazardous materials are not expected and will not be further analyzed in the Draft EA.

Construction activities at the affected facilities that may occur as part of implementation of the proposed project may require grading, excavating, and trenching which could potentially uncover contaminated soils. In the event that any excavated soils contain concentrations of certain substances, including heavy metals and hydrocarbons, the handling, processing, transportation and disposal of the contaminated soils will be subject to multiple hazardous waste regulations such as Title 22 of the California Code of Regulations and other local and federal rules. Title 22 has multiple requirements for hazardous waste handling, transport and disposal, such as requirements to used approved disposal and treatment facilities, to use certified hazardous waste transporters, and to have manifests for tracking the hazardous materials. If contaminated soils are encountered during grading, excavating, and trenching, the soils would need to be removed for proper decontamination and disposal in accordance with SCAQMD Rule 1166 – Volatile Organic Compound Emissions From Decontamination of Soil. Therefore, impacts related to soil contamination will be addressed in the Draft EA.

VIII. e) & f) Construction activities from implementing the proposed project are expected to occur within the existing confines of the affected facilities. However, some of these facilities may be located within two miles of an airport (either public or private) and are located within an airport land use plan. Nonetheless, the installation of the SOx control devices is expected to be constructed according to the all appropriate building, land use and fire codes and operated at a low enough height relative to existing flight patterns so that the structure would not interfere with plane flight paths consistent with Federal Aviation Regulation, Part 77. Such codes are designed to protect the public from hazards associated with normal operation. Therefore, the proposed project is not expected to result in a safety hazard for people residing or working in the area of the affected facilities even within the vicinity of an airport and as such, will not be further analyzed in the Draft EA.

VIII. g) Emergency response plans are typically prepared in coordination with the local city or county emergency plans to ensure the safety of not only the public (surrounding local communities), but the facility employees as well. The proposed project would not impair implementation of, or physically interfere with any adopted emergency response plan or emergency evacuation plan. The existing industrial facilities affected by the proposed project would typically already have their own emergency response plans in place. However, for those

operators of affected facilities who elect to install SOx control technology may need to update their emergency response plan. Thus, the proposed project is not expected to impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan and as such, will not be further analyzed in the Draft EA.

VIII. h) & i) The Uniform Fire Code and Uniform Building Code set standards intended to minimize risks from flammable or otherwise hazardous materials. Local jurisdictions are required to adopt the uniform codes or comparable regulations. Local fire agencies require permits for the use or storage of hazardous materials and permit modifications for proposed increases in their use. Permit conditions depend on the type and quantity of the hazardous materials at the facility. Permit conditions may include, but are not limited to, specifications for sprinkler systems, electrical systems, ventilation, and containment. The fire departments make annual business inspections to ensure compliance with permit conditions and other appropriate regulations. Further, businesses are required to report increases in the storage or use of flammable and otherwise hazardous materials to local fire departments. Local fire departments ensure that adequate permit conditions are in place to protect against potential risk of upset.

The proposed project is not expected to increase the existing risk of fire hazards in areas with flammable brush, grass, or trees. Additional natural gas may be used during both construction and operation of the proposed project. Natural gas is currently used at all of the affected facilities. The hazards associated with natural gas would result in a torch fire in the event that a release occurred and caught fire. Because of the locations of each facility that would be affected by the proposed project, a torch fire would be expected to remain on-site so that there would be no public exposure to the fire hazards. No substantial or native vegetation typically exists on or near the affected facilities (specifically because they could be a fire hazard) so the proposed project is not expected to expose people or structures to wild fires. Therefore, no significant increase in fire hazards are expected any of the affected facilities associated with implementing the proposed project.

Based on these considerations, the potential hazards impacts related to the construction and operations at each affected facility and the transport of hazardous materials associated with the proposed project will be addressed in the Draft EA.

	Potentially Significant Impact	**Less Than Significant Impact**	**No Impact**
IX. HYDROLOGY AND WATER QUALITY. Would the project:			
a) Violate any water quality standards or waste discharge requirements?	☑	☐	☐

		Potentially Significant Impact	Less Than Significant Impact	No Impact
b)	Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g. the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?	☐	☑	☐
c)	Substantially alter the existing drainage pattern of the site or area, including through alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site?	☐	☑	☐
d)	Substantially alter the existing drainage pattern of the site or area, including through alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site?	☐	☑	☐
e)	Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?	☐	☑	☐
f)	Otherwise substantially degrade water quality?	☑	☐	☐
g)	Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?	☐	☐	☑
h)	Place within a 100-year flood hazard area structures which would impede or redirect flood flaws?	☐	☐	☑
i)	Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?	☐	☐	☑
j)	Inundation by seiche, tsunami, or mudflow?	☐	☐	☑

		Potentially Significant Impact	Less Than Significant Impact	No Impact
k)	Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?	☑	☐	☐
l)	Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☑	☐	☐
m)	Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☑	☐
n)	Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?	☑	☐	☐
o)	Require in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?	☑	☐	☐

Significance Criteria

Potential impacts on water resources will be considered significant if any of the following criteria apply:

Water Quality:

- The project will cause degradation or depletion of ground water resources substantially affecting current or future uses.
- The project will cause the degradation of surface water substantially affecting current or future uses.
- The project will result in a violation of National Pollutant Discharge Elimination System (NPDES) permit requirements.
- The capacities of existing or proposed wastewater treatment facilities and the sanitary sewer system are not sufficient to meet the needs of the project.
- The project results in substantial increases in the area of impervious surfaces, such that interference with groundwater recharge efforts occurs.
- The project results in alterations to the course or flow of floodwaters.

Water Demand:

- The existing water supply does not have the capacity to meet the increased demands of the project, or the project would use a substantial amount of potable water.
- The project increases demand for water by more than five million gallons per day.

Discussion

IX. a), f), k), l) & o) Operators of facilities affected by the proposed project are expected to install new air pollution control equipment, such as wet gas scrubbers, to reduce SOx emissions. Operational activities associated with wet gas scrubbers will increase the demand for water and subsequently, will increase the amount wastewater discharged at each affected facility. In addition, construction activities associated with the proposed project may require the use of water as a dust suppressant, if grading is required. The impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be potentially significant. Thus, the potential impact of the increase in water demand and wastewater discharge will be evaluated in the Draft EA.

IX. b) Implementation of the proposed project is not expected to significantly adversely affect the quantity or quality of groundwater in the area of each affected facility. No significant adverse impacts are expected to ground water quality from the proposed project because: 1) wastewater will continue to be collected and treated in each of the affected facility's wastewater treatment systems or in compliance with the current wastewater discharge permits, as applicable; 2) no underground storage tanks are expected to be constructed as part of the proposed project; 3) containment berms will be required or may already exist around any new or modified units to minimize the potential for a spill to contaminate soil and groundwater; and, 4) any new storage tanks that may be proposed will be required to comply with BACT and other safety requirements such as double bottom and monitoring requirements.

IX. c), d), e) & m) Changes to each affected facility's storm water collection systems are expected to be less than significant since most of the changes associated with the proposed project will occur within existing units (i.e., by installing SOx control equipment). Further, typically most of the areas likely to be affected by the proposed project are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each facility's current wastewater treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions. Storm water Pollution Prevention Plans may need to be updated, as necessary to reflect operational modifications and included additional Best Management Practices, if required. Therefore, less than significant storm water quality impacts are expected to result from the operation of the proposed project.

IX. g), h), & i) The proposed project is expected to involve construction and modification activities located within the confines of existing facilities and does not include the construction of any new housing so it would not place new housing within a 100-year flood hazard area. It is likely that most affected facilities are not located within a 100-year flood hazard area. Any affected facilities that may be located in a 100-year flood area could impede or redirect 100-year flood flows, but this would be considered part of the existing setting and not an effect of the proposed project. Since the proposed project would not require locating new facilities within a flood zone, it is not expected that implementation of the proposed project would expose people or property to any known water-related flood hazards.

IX. j) The proposed project does not require construction of new facilities in areas that could be affected by tsunamis. Of the facilities affected by the proposed project, some are located near the Ports of Long Beach, Los Angeles, and San Pedro. The port areas are protected from tsunamis by the construction of breakwaters. Construction of breakwaters combined with the distance of each facility from the water is expected to minimize the potential impacts of a tsunami or seiche so that no significant impacts are expected. The proposed project does not require construction of facilities in areas that are susceptible to mudflows (e.g., hillside or slope areas). Existing affected facilities that are currently located on hillsides or slope areas may be susceptible to mudflow, but this would be considered part of the existing setting. As a result, the proposed project is not expected to generate significant adverse mudflow impacts.

IX. n) Each affected facility may not have sufficient water supplies available for implementing the proposed project since the type of air pollution control equipment that would be installed at the affected facilities (e.g., wet gas scrubbers) heavily rely on water as part of the control process. Also, limited water demand increases may occur for dust suppression during site preparation/grading activities. Thus, the need for new or expanded water supply entitlements may be necessary. While it is not possible to predict water availability in the future, existing entitlements and resources in the district are currently at drought levels. Thus, the water demand that would result from implementing the proposed project may result in significant adverse water impacts.

Based upon these considerations, the potential hydrology and water quality impacts, especially those associated with wastewater discharge and water demand are expected to be significant and will be evaluated in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
X.	**LAND USE AND PLANNING.** Would the project:			
a)	Physically divide an established community?	☐	☐	☑
b)	Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?	☐	☐	☑
c)	Conflict with any applicable habitat conservation or natural community conservation plan?	☐	☐	☑

Significance Criteria
Land use and planning impacts will be considered significant if the project conflicts with the land use and zoning designations established by local jurisdictions.

Discussion

X. a) The proposed project does not require the construction of new facilities, but any physical effects that will result from the proposed project, will occur at existing industrial facilities. Thus, implementing the proposed project will not result in physically dividing any established communities.

X. b) & c) There are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments and no land use or planning requirements will be altered by the proposed project. Further, the proposed project would be consistent with the typical industrial zoning of the affected facilities. Typically, all proposed construction activities are expected to occur within the confines of the existing facilities. The proposed project would not affect in any way habitat conservation or natural community conservation plans, agricultural resources or operations, and would not create divisions in any existing communities. Further, no new development or alterations to existing land designations will occur as a result of the implementation of the proposed project. Therefore, present or planned land uses in the region will not be affected as a result of implementing the proposed project.

Based upon these considerations, significant land use planning impacts are not expected from the implementation of the proposed project, and thus, will not be further analyzed in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
XI. MINERAL RESOURCES. Would the project:			
a) Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?	☐	☐	☑
b) Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan?	☐	☐	☑

Significance Criteria

Project-related impacts on mineral resources will be considered significant if any of the following conditions are met:

- The project would result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state.
- The proposed project results in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Discussion

XI. a) & b) There are no provisions in the proposed project that would result in the loss of availability of a known mineral resource of value to the region and the residents of the state such

as aggregate, coal, clay, shale, et cetera, or of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

Based upon these considerations, significant mineral resource impacts are not expected from the implementation of the proposed project, and thus, will not be further analyzed in the Draft EA.

		Potentially Significant Impact	Less Than Significant Impact	No Impact
XII.	**NOISE.** Would the project result in:			
a)	Exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?	☐	☑	☐
b)	Exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?	☐	☑	☐
c)	A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☑	☐
d)	A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☑	☐
e)	For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?	☐	☑	☐
f)	For a project within the vicinity of a private airship, would the project expose people residing or working in the project area to excessive noise levels?	☐	☑	☐

Significance Criteria

Impacts on noise will be considered significant if:

- Construction noise levels exceed the local noise ordinances or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three decibels (dBA) at the site boundary. Construction noise levels will be considered significant if they exceed federal Occupational Safety and Health Administration (OSHA) noise standards for workers.

- The proposed project operational noise levels exceed any of the local noise ordinances at the site boundary or, if the noise threshold is currently exceeded, project noise sources increase ambient noise levels by more than three dBA at the site boundary.

Discussion

XII. a), b), c), & d) Modifications or changes associated with the implementation of the proposed project will take place at existing facilities that are located in industrial settings. The existing noise environment at each of the affected facilities is typically dominated by noise from existing equipment onsite, vehicular traffic around the facilities, and trucks entering and exiting facility premises. Construction activities associated with implementing the proposed project may generate some noise associated with the use of construction equipment and construction-related traffic. However, noise from the proposed project is not expected to produce noise in excess of current operations at each of the existing facilities. If SOx control devices are installed, the operations phase of the proposed project may add new sources of noise to each affected facility. However, it is expected that each facility affected will comply with all existing noise control laws or ordinances. Further, Occupational Safety and Health Administration (OSHA) and California-OSHA (Cal/OSHA) have established noise standards to protect worker health. These potential noise increases are expected within the allowable noise levels established by the local noise ordinances for industrial areas, and thus are expected to be less than significant. Therefore, potential noise impacts will not be further evaluated in the Draft EA.

XII. e) & f) Though some of the facilities affected by the proposed project are located at sites within an airport land use plan, or within two miles of a public airport, the addition of SOx control equipment would not expose people residing or working in the project area to the same degree of excessive noise levels associated with airplanes. All noise producing equipment must comply with local noise ordinances and applicable OSHA or Cal/OSHA workplace noise reduction requirements.

Based upon these considerations, significant noise impacts are not expected from the implementation of the proposed project and will not be further analyzed in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
XIII. POPULATION AND HOUSING. Would the project:			
a) Induce substantial growth in an area either directly (for example, by proposing new homes and businesses) or indirectly (e.g. through extension of roads or other infrastructure)?	☐	☐	☑
b) Displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere?	☐	☐	☑

		Potentially Significant Impact	Less Than Significant Impact	No Impact
c)	Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?	☐	☐	☑

Significance Criteria

Impacts of the proposed project on population and housing will be considered significant if the following criteria are exceeded:

- The demand for temporary or permanent housing exceeds the existing supply.
- The proposed project produces additional population, housing or employment inconsistent with adopted plans either in terms of overall amount or location.

Discussion

XIII. a) The construction activities associated with the proposed project at each affected facility are not expected to involve the relocation of individuals, require new housing or commercial facilities, or change the distribution of the population. The reason for this conclusion is that operators of affected facilities who need to perform any construction activities to comply with the proposed project can draw from the existing labor pool in the local southern California area. Further, it is not expected that the installation of the SOx control equipment will require new employees during operation of the equipment. In the event that new employees are hired, it is expected that the number of new employees at any one facility would be small. Human population within the jurisdiction of the SCAQMD is anticipated to grow regardless of implementing the proposed project. As a result, the proposed project is not anticipated to generate any significant adverse effects, either direct or indirect, on population growth in the district or population distribution.

XIII. b) & c) Because the proposed project includes modifications and/or changes at existing facilities located in industrial settings, the proposed project is not expected to result in the creation of any industry that would affect population growth, directly or indirectly induce the construction of single- or multiple-family units, or require the displacement of people or housing elsewhere in the district.

Based upon these considerations, significant population and housing impacts are not expected from the implementation of the proposed project and will not be further evaluated in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
XIV. PUBLIC SERVICES. Would the proposal result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the following public services:			
a) Fire protection?	☐	☐	☑
b) Police protection?	☐	☐	☑
c) Schools?	☐	☐	☑
d) Parks?	☐	☐	☑
e) Other public facilities?	☐	☐	☑

Significance Criteria
Impacts on public services will be considered significant if the project results in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, or the need for new or physically altered government facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response time or other performance objectives.

Discussion
XIV. a) & b) Implementation of the proposed project is expected to cause facility operators to install SOx control devices, all the while continuing current operations at existing affected facilities. The proposed project may result in a greater demand for catalyst and scrubbing agents, which will need to be transported to the affected facilities that install SOx controls and stored onsite prior to use. In the event of an accidental release, fire departments are typically first responders for control and clean-up and police may be need to be available to maintain perimeter boundaries. Based on the low probability of accidental releases of catalysts and scrubbing agents occurring, the proposed project is not expected to increase the need or demand for additional public services (e.g., fire departments, police departments, schools, parks, government, et cetera) above current levels.

XIV. c) & d) As noted in the previous "Population and Housing" discussion, the proposed project is not expected to induce population growth in any way because the local labor pool (e.g., workforce) is expected to be sufficient to accommodate any construction activities that may be necessary at affected facilities and operation of new SOx control equipment is not expected to require additional employees. Therefore, there will be no increase in local population and thus no impacts are expected to local schools or parks.

XIV. e) The proposed project is expected to result in the use of new or modified add-on control equipment for SOx control. Besides permitting the equipment or altering permit conditions by the SCAQMD, there is no need for other types of government services. The proposed project would not result in the need for new or physically altered government facilities in order to maintain acceptable service ratios, response times, or other performance objectives. There will be no increase in population and, therefore, no need for physically altered government facilities.

Based upon these considerations, significant public services impacts are not expected from the implementation of the proposed project and will not be further evaluated in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
XV. RECREATION.			
a) Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?	☐	☐	☑
b) Does the project include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment?	☐	☐	☑

Significance Criteria

Impacts to recreation will be considered significant if:

- The project results in an increased demand for neighborhood or regional parks or other recreational facilities.
- The project adversely affects existing recreational opportunities.

Discussion

XV. a) & b) As discussed previously under "Land Use," there are no provisions in the proposed project that would affect land use plans, policies, or regulations. Land use and other planning considerations are determined by local governments; no land use or planning requirements will be altered by the proposed project. Further, the proposed project would not increase the use of existing neighborhood and regional parks or other recreational facilities or include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment because the proposed project is not expected to induce population growth.

Based upon these considerations, significant public services impacts are not expected from the implementation of the proposed project and will not be further evaluated in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
XVI. SOLID/HAZARDOUS WASTE. Would the project:			
a) Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?	☐	☑	☐
b) Comply with federal, state, and local statutes and regulations related to solid and hazardous waste?	☐	☑	☐

Significance Criteria

The proposed project impacts on solid/hazardous waste will be considered significant if the following occurs:

- The generation and disposal of hazardous and non-hazardous waste exceeds the capacity of designated landfills.

Discussion

XVI. a) Construction activities associated with installing SOx control equipment such as wet gas scrubbers, demolition and site preparation/grading/excavating could generate solid waste as result of implementing the proposed project. Demolition activities could generate demolition waste while site preparation, grading, and excavating could uncover contaminated soils since the facilities affected by the proposed project are located in existing industrial areas. Excavated soil, which may be contaminated, will need to be characterized, treated, and disposed of offsite in accordance with applicable regulations. Where appropriate, the soil will be recycled if it is considered or classified as non-hazardous waste or it can be disposed of at a landfill that accepts non-hazardous waste. Otherwise, the material will need to be disposed of at a hazardous waste facility. (Potential soil contamination is addressed in the Hazards/Hazardous Materials discussion in Section VIII. d.)

Solid or hazardous wastes generated from construction-related activities would consist primarily of materials from the demolition of existing air pollution control equipment and construction associated with new air pollution control equipment. Construction-related waste would be disposed of at a Class II (industrial) or Class III (municipal) landfill. There are 48 Class II/Class III landfills within the SCAQMD's jurisdiction. The estimated total capacity of these landfills is approximately 111,198 tons per day (SCAQMD, 2000). For these reasons, the construction impacts of the proposed project on waste treatment/disposal facilities are expected to be less than significant.

During operation of the SOx control equipment, the use of catalyst is expected to increase but the generation of catalyst fines is expected to be captured by the control equipment as wet solids. These wet catalyst solids can be collected for recycling for use in manufacturing cement. Therefore, less than significant adverse impacts to non-hazardous waste disposal facilities are expected from operational activities associated with the proposed project.

It is possible that some, if not all, of the affected facilities will address any increase in waste through their existing waste minimization plans. In addition, other affected facilities that have

existing catalyst-based operations currently regenerate, reclaim or recycle the catalysts, in lieu of disposal. Moreover, due to the heavy metal content and its relatively high cost, catalyst recycling can be a lucrative choice. Depending on operating conditions, it is expected that spent catalysts would be reclaimed and recycled, though it is possible that spent catalysts could be disposed of. The composition of the catalyst will determine in which type of landfill a catalyst would be disposed.

Based on the preceding discussion, it is likely that spent catalysts would be considered a "designated waste," which is characterized as a non-hazardous waste consisting of, or containing pollutants that, under ambient environmental conditions, could be released at concentrations in excess of applicable water objectives, or which could cause degradation of the waters of the state (California Code of Regulations, Title 23, Chapter 3 Subparagraph 2522(a)(1)). Depending on its actual waste designation, spent catalysts would likely be disposed of in a Class II landfill or a Class III landfill that is fitted with liners. According to the Program EIR for the 2007 AQMP (SCAQMD, 2007), total Class III landfill waste disposal capacity in the district is approximately 97,269 tons per day, many of which have liners and can handle Class II and Class III wastes.

Disposal of spent catalyst would typically involve crushing the material and encasing it in concrete prior to disposal. Since it is expected that most spent catalysts will be recycled and regenerated, it is anticipated that there will be sufficient landfill capacity in the district to accommodate disposal of any spent catalyst materials. Thus, the potential increase of solid waste generated by the air pollution control equipment operated at the 12 affected facilities that are expected to install SOx control equipment as a result implementing the proposed project may not necessarily be disposed of and, therefore, is not expected to exceed the capacity of designated landfills available to each affected facility.

XVI. b) Implementing the proposed project is not expected to hinder in any way any affected facility's ability to comply with existing federal, state, and local regulations related to solid and hazardous wastes.

Based upon these considerations, significant solid/hazardous waste impacts are not expected from the implementation of the proposed project and will not be further evaluated in the Draft EA.

	Potentially Significant Impact	**Less Than Significant Impact**	**No Impact**
XVII. TRANSPORTATION/TRAFFIC. Would the project:			
a) Cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections)?	☑	☐	☐

		Potentially Significant Impact	Less Than Significant Impact	No Impact
b)	Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways?	☑	☐	☐
c)	Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?	☐	☑	☐
d)	Substantially increase hazards due to a design feature (e.g. sharp curves or dangerous intersections) or incompatible uses (e.g. farm equipment)?	☐	☐	☑
e)	Result in inadequate emergency access?	☐	☑	☐
f)	Result in inadequate parking capacity?	☐	☑	☐
g)	Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g. bus turnouts, bicycle racks)?	☐	☑	☐

Significance Criteria

Impacts on transportation/traffic will be considered significant if any of the following criteria apply:

- Peak period levels on major arterials are disrupted to a point where level of service (LOS) is reduced to D, E or F for more than one month.
- An intersection's volume to capacity ratio increase by 0.02 (two percent) or more when the LOS is already D, E or F.
- A major roadway is closed to all through traffic, and no alternate route is available.
- There is an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system.
- The demand for parking facilities is substantially increased.
- Water borne, rail car or air traffic is substantially altered.
- Traffic hazards to motor vehicles, bicyclists or pedestrians are substantially increased.
- The need for more than 350 employees
- An increase in heavy-duty transport truck traffic to and/or from the facility by more than 350 truck round trips per day
- Increase customer traffic by more than 700 visits per day.

Discussion

XVII. a) & b) Construction activities resulting from implementing the proposed project may generate a temporary increase in traffic in the areas of each affected facility associated with construction workers, construction equipment, and the delivery of construction materials. Also, the proposed project may exceed, either individually or cumulatively, the current level of service of the areas surrounding the affected facilities. The impacts of the traffic load and capacity of the street system during construction will be analyzed in the Draft EA.

The work force at each affected facility is not expected to significantly increase during operations of the proposed project operations because few, if any, new employees are expected to be needed to operate potential SOx control equipment. As a result, operation-related traffic is expected to be limited more towards supply deliveries, but less than significant. Thus, the operational traffic impacts will not be evaluated further in the Draft EA.

XVII. c) Though some of the facilities that will be affected by the proposed project are located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, actions that would be taken to comply with the proposed project, such as installing SOx control equipment, are not expected to significantly influence or affect air traffic patterns. Further, the size and type of air pollution control devices that would be installed would not be expected to affect navigable air space. Thus, the proposed project would not result in a change in air traffic patterns including an increase in traffic levels or a change in location that results in substantial safety risks.

XVII. d) & e) The siting of each affected facility is consistent with surrounding land uses and traffic/circulation in the surrounding areas of the affected facilities. Thus, the proposed project is not expected to substantially increase traffic hazards or create incompatible uses at or adjacent to the affected facilities. Aside from the temporary effects due to a slight increase in truck traffic for those facilities that will undergo construction activities during installation of air pollution control equipment, the proposed project is not expected to alter the existing long-term circulation patterns. Further, the proposed project is not expected to require a modification to circulation, thus, no long-term impacts on the traffic circulation system are expected to occur. The proposed project is not expected to involve the construction of any roadways, so there would be no increase in roadway design feature that could increase traffic hazards. Emergency access at each affected facility is not expected to be impacted by the proposed project. Further, each affected facility is expected to continue to maintain their existing emergency access gates.

XVII. f) Each affected facility will be required to provide parking for the construction workers, as applicable, either on or within close proximity to each facility. No additional parking will be needed after completion of the construction phase because the work force at each facility is not expected to significantly increase as a result of implementing the proposed project.

XVII. g) Construction and operation activities resulting from implementing the proposed project are not expected to conflict with policies supporting alternative transportation since the proposed project does not involve or affect alternative transportation modes (e.g. bicycles or buses) because the construction and operation activities related to the proposed project will occur solely in existing industrial areas.

Based upon these considerations, significant transportation/traffic impacts are not expected from the implementation of the proposed project and will not be further evaluated in the Draft EA.

	Potentially Significant Impact	Less Than Significant Impact	No Impact
XVIII. MANDATORY FINDINGS OF SIGNIFICANCE.			
a) Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory?	☐	☐	☑
b) Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)	☑	☐	☐
c) Does the project have environmental effects that will cause substantial adverse effects on human beings, either directly or indirectly?	☑	☐	☐

Discussion

XVIII. a) The proposed project is not expected to reduce or eliminate any plant or animal species or destroy prehistoric records of the past. As indicated in the biological resources discussion, each site affected by the proposed project is part of an existing facility, which has been previously graded, such that the proposed project is not expected to extend into environmentally sensitive areas.

XVIII. b) The Environmental Checklist indicates that the proposed project has potentially significant adverse impacts on aesthetics, air quality, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic. The potential for cumulative impacts on these resources will be evaluated in the Draft EA.

XVIII. c) Even though the objective of the proposed project is to reduce SOx emissions from the top emitters in the RECLAIM program, the proposed project may result in secondary effects, emissions of regulated air pollutants, toxic air contaminants, GHGs and may also increase the hazards at some of the affected facilities. The potential for these impacts to have adverse impacts on human beings, either directly or indirectly, will be evaluated in the Draft EA.

A P P E N D I X A (of the Initial Study)

P R O P O S E D A M E N D E D R E G U L A T I O N X X:

Proposed Amended Rule 2002

In order to save space and avoid repetition, please refer to the latest version of proposed amended Rule 2002 located elsewhere in Appendix A of the Draft EA. The June 9, 2009 version of the proposed amended rule was circulated with the Notice of Preparation/Initial Study (NOP/IS) that was released on June 19, 2009 for a 30-day public review and comment period ending July 21, 2009.

Original hard copies of the NOP/IS, which include the version of the proposed amended rule listed above, can be obtained through the SCAQMD Public Information Center at the Diamond Bar headquarters or by calling (909) 396-2039.

APPENDIX D

COMMENT LETTERS ON THE NOP/INITIAL STUDY AND RESPONSES TO COMMENTS

July 21, 2009

Barbara Radlein
Air Quality Specialist
South Coast Air Quality Management District
21865 Copley Drive
Diamond Bar, CA 91765-4182

Dear Ms. Radlein,

Chevron is pleased to have the opportunity to review and comment on the *Initial Study for Proposed Amended Regulation XX.* Chevron believes that the potential cumulative impact of the recommended SOx control measures is so great that the project should be reviewed in detail. Chevron recommends that the environmental review place significant emphasis on the issues listed below. 1-1

AESTHETICS:

1. The Environmental Assessment (EA) should address to aesthetic impact of multiple moisture plumes rising all over the south bay. Additionally the EA should recognize that there plumes will appear dark at night and cloudy days giving the appearance of massive amounts of emissions being emitted at night. 1-2
2. The EA should analyze cumulative aesthetic impacts from all potential projects resulting from the amendment of Regulation XX. 1-3

AIR QUALITY (AQ)

1. In order to employ some of the recommended technologies, it may be necessary to reheat certain exhaust to properly operate the SOx control equipment. This reheating will resulting additional construction activities and additional green house emissions as a result of fuel combustion for this reheating. These related AQ impacts should also be considered in the EA. 1-4
2. Consistent with point 2 above; all potential projects resulting from the adoption of this regulation should be analyzed together to determine individual and cumulative impacts of all pollutants. 1-5
3. All alternatives to stationary source reductions and mitigation measures must be analyzed for increases in other pollutants as a result of RECLAIM SOX shave. 1-6
4. Due to the above mentioned contributing issues and the complex and over lapping nature of this project, we recommend that the EA include the full PM2.5 and RECLAIM programs in order to capture all potential future projects. 1-7
5. Solid waste transportation from these proposed recommendations will create an ongoing source of vehicle emissions from trucks, including NOx, CO, VOC, TAC, PM and SOx. 1-8

Barbara Radlein
South Coast Air Quality Management District
July 21, 2009
Page 2

ENERGY.

1. The implementation of the recommended emission reduction technologies will impact all regulated facilities and may require significant electrical, natural gas and other infrastructure improvements to accommodate the energy demands of the new equipment. There appears to be a serious deficiency in the analysis of the full energy impacts of these technology recommendations in Part II of the draft Staff Report. 1-9
2. The energy requirements for these recommendations may require the facilities to install new transformer stations to supply the required power, adding to the construction activities. 1-10

HAZARDS AND HAZARDOUS MATERIAL

1. Installation of the proposed measures would result in an increase of hazardous material transported to and stored at the facility, as well as, hazardous waste stored at and transported from the facilities. 1-11
2. The increased transportation of hazardous materials and hazardous wastes greatly increases the risk accidental spills and releases at the facility and on public roadways. 1-12

HYDROLOGY AND WATER QUALITY

1. The third-party consultant reports which the SCAQMD staff has established as the primary resource for technology recommendations and establishing BARCT levels, outlines the tremendous potential water use impacts associated with employment of "gas scrubbing" technologies. It should be noted that these water consumption impacts are associated with all three scrubber technologies, not just the wet-gas scrubbers. 1-13
2. A review of the recommendations of wet gas scrubbers for the FCCUs and SRUs indicates a potential for excessive water usage, with fresh water demand estimated as high as 90 million gallons per year for each scrubber. 1-14
3. Due to the large size of scrubbers involved, it appears that they would represent the top end of the stated ranges – and this is almost certainly true for NWGSs on FCCUs. Thus, the total impact would be a potential new demand for fresh water as high as one billion gallons per year (90 million gallons and 12 installations) 1-15
4. Waste water is estimated at up to 40 million gallons per year for each installation, This increased wastewater load on Publicly Owned Treatment Plants (POTWs) could be as high as 440 million gallons per year (40 million gallons and an assumed eleven systems that would discharge to a POTW). This could result in substantial cost for upgrades at some POTWs. 1-16
5. The EA must consider that one facility would be required to re-open an existing NPDES permit to request an increase in discharge of wastewater flow to the Santa Monica bay, this revision is almost certain to be rejected. 1-17
6. It is expected that this project will increase the levels of sulfite, sulfate, COD, total suspended solids, pH, and DEA at the facility's wastewater treatment plant. Additionally the potential for wastewater to require pre-treatment prior to discharge, may require hazardous treatment permitting and additional construction and spill/contaminations potential due to these activities. 1-18
7. These are dramatic resource consumption and waste figures and these considerations have clearly not been adequately addressed in the District's BARCT recommendations. We strongly suggest 1-19

that the EA conduct a thorough and multi-faceted analysis of all potential multi-media impacts associated with the current technologies employment. 1-19 Cont'd

MANDATORY FINDINGS OF SIGNIFICANCE

1. Overall, implementation of the proposed measures will have significant impact to water and energy demands at the affected facilities. The increased level of hazardous materials being transported over local roads and through neighborhood may greatly increase the risk of accidental release and exposure. 1-20
2. The increased discharge of industrial wastewater may affect a POTW's ability to handle the additional flows and properly treat the water prior to release. 1-21
3. The aesthetic impact of multiple plumes arising from a facility will negatively impact the views and skyline in the adjoining areas. It should be noted that the refineries have multiple sulfur recovery trains that may each require a separate wet gas scrubber resulting in additional plumes. 1-22

Chevron appreciates this opportunity to provide you our perspective and we look forward to developing a comprehensive Environmental Assessment considering all the relevant issues. Should you have any questions please feel free to contact either myself, or Mr. Robert Orinion at (310) 615-4147.

Sincerely,

Chris Manzanares

Responses to Comment Letter #1
(Chevron, July 21, 2009)

1-1 The CEQA analysis in the PEA will focus on the following environmental topics: aesthetics, air quality, energy, hazards and hazardous materials, hydrology and water quality, and transportation. For any topic that is shown to have significant adverse impacts, a cumulative impacts analysis will also be included in the PEA.

1-2 The Aesthetics discussion in Chapter 4 of the PEA contains an analysis for the installation and operation of 11 wet gas scrubbers (WGSs) with 11 corresponding steam plumes. While it is true that the appearance of the steam plumes from WGSs may vary, depending on atmospheric conditions such as temperature, pressure and humidity as well as time of day, the steam plume is primarily steam (water vapor), not emissions. See also the response to Comment 1-22.

1-3 Because the project-specific aesthetic impacts were shown to not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative aesthetics impacts..

1-4 The commenter did not specify a particular technology that would require inlet gas to be reheated, but for refinery operations, WGSs, as the primary SOx control equipment under consideration for the proposed project, typically do not need a high temperature inlet gas stream. Thus, contrary to the comment, reheating would not be necessary and there will be no construction activities or GHG emissions associated with reheating activities.

1-5 The PEA contains a comprehensive analysis of the individual effects of the entire project and the cumulative effects for topics that are shown to have significant adverse impacts, both on a facility-by-facility basis, as well as on a source-category basis, for each of the following environmental topics: aesthetics, air quality, energy, hazards and hazardous materials, hydrology and water quality, and transportation.

1-6 An alternatives analysis for the proposed project has been prepared and can be found in Chapter 5 of the PEA.

1-7 Impacts from all criteria pollutants, including PM 2.5, and GHGs have been analyzed in the PEA for all affected facilities. Regarding the commenter's suggestion that all potential future projects be analyzed, the PEA takes into account the potential effects of the proposed project spanning to 2019 at which time all projects required to implement the rule are expected to be completed. To consider potential future projects beyond that timeframe would be considered too speculative to evaluate pursuant to CEQA Guidelines §15145.

1-8 The proposed project is expected to have air quality impacts from transportation activities associated with supply deliveries and disposal activities from increased truck trips. In addition, the proposed project is expected to have transportation impacts due to the increased number of trucks on the road to accommodate the additional delivery and disposal trips. Both of these circumstances have been analyzed; the commenter is referred to the Air Quality and Transportation/Traffic discussions in Chapter 4 of the PEA.

1-9 Chapter 4 of the PEA contains a comprehensive energy analysis of the effects of the entire project on an individual facility basis as well as on a source category basis. Contrary to the unsubstantiated assumption that the proposed project would require energy infrastructure improvements, the energy analysis shows that the proposed project will have less than significant impacts for energy, including the use of natural gas, electricity, and fuel (gasoline and diesel.) The energy analysis in both the PEA and the Draft Staff Report are based on data taken from the consultants' reports.

1-10 The consultant's report did not indicate a need to install new transformer stations to supply the required power to operate the new SOx controls. Further, in the energy discussion in Chapter 4 of the PEA, the analysis shows an overall modest, less than significant increase in electricity demand of approximately 204 MWh/day under Option 1 and 101 MWh/day under Option 2, with the highest demand of 48 MWh/day occurring at Facility B under Option 1 and 23 MWh/day occurring at Facility K under Option 2. Refer to Tables 4-19 to 4-22 for the summaries of the energy demand on a facility-by-facility and source category basis.

1-11 The hazards/hazardous materials discussion in Chapter 4 of the PEA analyzes the potential increase in transportation, storage and use of hazardous substances that may be needed as well as the generation, storage and transport of hazardous waste that may result from operating SOx control technologies.

1-12 Regarding transportation of hazardous materials and hazardous wastes, see the response to Comment 1-11.

1-13 Projected total water demand impacts were provided by the consultants for multiple technologies, not just wet gas scrubbers. While most of the total water demand impacts come from the WGSs, other technologies also contributed to the overall water demand impacts analysis in the Hydrology/Water Quality discussion in Chapter 4 of the Draft PEA.

1-14 Contrary to the comment, the total water demand was estimated to be 241,096 gallons per day (or 88 million gallons per year) for four WGSs installed at four FCCUs and 354,247 gallons per day (or 129 million gallons per year) for three WGSs installed at three SRUs, not 90 million gallons per year for <u>each</u> WGS. Because WGS technology does not require fresh or potable water for its operations, recycled or reclaimed water can be utilized to satisfy the total water demand. Further, facilities that currently obtain recycled or industrial-use water for their industrial processes will be required to continue to do so in accordance with the California Water Code if there is a need to increase water use as part of the proposed project. Based on this understanding, the analysis shows that 147,945 gallons per day (or 54 million gallons per year) can currently be supplied by recycled water for the FCCUS. Similarly, all 354,247 gallons per day (or 129 million gallons per year) for three WGSs installed at three SRUs can also be supplied by recycled water. Lastly, the remaining 93,151 gallons per day (34 million gallons per year) of recycled water may also be supplied to the WGSs for the FCCUs after completion of the LADWP's HRRWPP project in Summer 2013. Since construction of the proposed project is not expected to begin sooner than 2012, most of the recycled water is expected to be available and could be utilized for all four WGSs and for most if not all of the FCCUs. In other words, 100

percent of the water demand for WGSs for both FCCUs and SRUs could be supplied by recycled, not potable (fresh), water.

1-15 Contrary to the comment, only four WGSs are projected to be installed on four FCCUs, not 12. Regarding the water demand estimates for WGSs for FCCUs, see the response to Comment 1-14.

For the entire project (which includes the FCCUs), 11 WGSs and two DGSs are projected to be installed for multiple source categories. Contrary to the comment, the worst-case total water demand and potable water demand would occur under Option 1 of the proposed project and would be would be approximately 883,368 gallons per day (322 million gallons per year), not one billion gallons per year. Of this amount, only 201,587 gallons per day or 74 million gallons per year under Option 1 (23 percent) is expected to be supplied by potable (fresh) water with the remainder being supplied by recycled water (63 percent) and industrial-use groundwater (14 percent).

1-16 Contrary to the comment, the wastewater estimates for the proposed project is approximately 270,532 gallons per day or 99 million gallons per year under Option 1 and 158,203 gallons per day or 58 million gallons per year under Option 1), not 40 million gallons per year for each installation (or 480 million gallons per year for the entire project based on the commenter's assumption of 12 installations). Further, the analysis shows that on a facility-by-facility basis, the proposed wastewater increases will not trigger a revision to any facility's wastewater permit. Lastly, SCAQMD staff has shared this data with the various sanitation districts and their staff has indicated that their facilities are expected to be able to handle the proposed increase in wastewater discharge.

1-17 Regarding the comment about the necessity of re-opening of an existing wastewater discharge permit for one facility, see the response to Comment 1-16.

1-18 If a WGS is installed as a result of implementing the proposed project, a liquid discharge containing captured pollutants will be generated. To process this discharge, the wet gas scrubber is designed with a purge treatment system that typically consists of a clarifier, an oxidation tank, and a wet fines tank to handle the wastewater from the scrubber before being sent to the facility's wastewater treatment plant. The purge treatment has two effluents, a liquid composed of water and sodium sulfate, and earth moist solids comprised of catalyst fines that have been captured from the flue gas. A clarifier utilizes a coagulant to separate and thicken the solids in the discharge; the thickened solids stream is collected, sent to a wet fines tank, and, if necessary, further dewatered in a roll-off bin. The concentrated solids slurry collected in both the wet fines tank and the roll-off bin are then transported by truck for disposal or recycling. The liquid that flows out of the clarifier is sent to an oxidation tank where the clarified liquid is oxidized for pH control and for reduction of the chemical oxygen demand (COD). The treated clear liquid is then passed to the existing refinery wastewater treatment system where it is treated before being discharged to a local sewage treatment plant. After the purge treatment is complete, the discharged scrubber water should contain total suspended solids of 200 ppm or less and the chemical oxygen demand from sulfites should be reduced to below 100 ppm. None of the byproducts in the discharged scrubber water or collected solids contain hazardous materials. In fact, the wet sulfate salts that are collected

from the scrubber water can be dried and sold as a commodity. Lastly, wet gas scrubbers for FCCUs at refineries use caustic such as NaOH for the process and not DEA, an amine scrubbing agent, as was implied by the comment.

1-19 Recognizing that WGS technology is a resource-intensive technology, SCAQMD staff has prepared this PEA to fully disclose the potential impacts associated with the proposed project. In particular, after conducting an extensive analysis in the PEA for hydrology and water quality, the analysis and data demonstrate that the commenter's water demand and wastewater assertions are exaggerated by over 300 percent for WGS technology.

1-20 Contrary to the comment, the analysis in the PEA for water quality, energy demand, and for hazards/hazardous materials demonstrates that the potential adverse impacts for these topics will be less than significant for the proposed project. However, the analysis in the PEA for water demand shows that the impacts will be potentially significant for potential potable water demand.

1-21 With regard to a POTW's ability to handle additional wastewater discharge, see the response to Comment 1-16.

1-22 The aesthetics analysis in the PEA considers steam plumes emanating from 11 WGSs and takes into account having multiple plumes from multiple WGSs installed at one facility. Contrary to the comment, if any WGS is installed as part of the proposed project at any of the affected facilities, the steam plume, though visible, is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant. Further, the visual continuity of the surrounding area is not expected to be adversely impacted because each WGS, if constructed, will be built within the confines of industrial areas and would be visually consistent with the profiles of the existing affected facilities. Thus, even if each WGS could be visible, depending on the location within each property boundary, the aesthetic significance criteria would not be exceeded.

Comment Letter #2

Western States Petroleum Association
Credible Solutions • Responsive Service • Since 1907

Jodie Muller
Manager, External Affairs and South Coast Region

July 21, 2009

Barbara Radlein
Air Quality Specialist
South Coast Air Quality Management District
21865 East Copley Drive
Diamond Bar, CA. 91765-4182

Dear Ms Radlein:

PRELIMINARY WSPA COMMENTS ON THE PROPOSED AMENDED REGULATION XX: REGIONAL CLEAN AIR INCENTIVES MARKET (RECLAIM) NOTICE OF PREPARATION/INITIAL STUDY

Thank you for the opportunity to comment on the Notice of Preparation and the Initial Study ("NOP/IS") for Proposed Amended Regulation XX. The Western States Petroleum Association ("WSPA") is a trade association that represents nearly thirty companies that conduct a substantial portion of the petroleum-related operations in California and the surrounding states. WSPA member companies own and operate facilities such as refineries in the South Coast Air Basin. As currently proposed, the amendments to Regulation XX rely heavily on the control of several refinery processes, and thus will have a substantial impact on WSPA member companies. WSPA offers the following comments for your consideration. WSPA will also prepare detailed comments to the draft environmental assessment when it is completed and available.

SCOPE OF THE ENIRONMENTAL ASSESSMENT

WSPA believes this major rule amendment will have widespread impacts to the residents, businesses, infrastructure and resources of the South Coast Air Basin. The NOP/IS identifies the topics of aesthetics, air quality, energy, hydrology and water quality, hazards and hazardous materials, and transportation/traffic as areas that may be adversely affected by the proposed project and will be further analyzed in the EA. WSPA concurs that these impacts should be further analyzed, and also agrees that the cumulative impacts on these environmental areas must be studied. 2-1

970 W. 190th Street, Suite 770, Torrance, California 90502
(310) 808-2143 • FAX: (310) 324-9063 • jodie@wspa.org • www.wspa.org

However, the District attempts to limit the scope of the EA by focusing merely on the examination of a few control options. In Chapter 2, ENVIRONMENTAL CHECKLIST AND DISCUSSION, the District states that "controlling emissions from equipment not operating at BARCT will be the most cost effective approach", and that therefore it will limit its analysis in the EA to those BARCT controls that it thinks are most likely to be implemented. WSPA contends that this assumption is flawed in nature and premature at best. At this point, the District is assuming a wide range of emission reductions, 3 to 8 tons of oxides of sulfur ("SO_x"), may be ultimately proposed in Regulation XX and has not determined over what time period the shave will be implemented. The amount of reductions targeted and the amount of time in which SO_x RECLAIM participants have to achieve the reductions will influence heavily the control options that will be implemented by industry to comply with the shave. Additionally, this assumption that a very few controls will be implemented ignores the fundamental premise of RECLAIM, that ultimately the market will determine the most cost-effective approaches to control. Instead, WSPA believes that the basis for determining which control options to analyze for purposes of an EA, should be those control options, or combinations thereof, that will have the greatest impact on the environment. The District should analyze the adverse impacts of all BARCT control options, as well as all other possible controls that may be implemented by SO_x RECLAIM participants to reduce SO_x emissions. The District should re-examine its NOP/IS to ensure that all adverse impacts have been identified for all possible control options. 2-2

Also, the impact of the current permit moratorium and the availability of emission offset credits for non-RECLAIM pollutants should be considered in determining cost-effectiveness, project start date and the overall environmental benefits the rule will achieve. The EA should analyze multimedia pollution impacts, project constraints imposed by existing environmental laws and regulations, and project impacts on new laws that will become effective in 2010 and beyond. The EA should also consider all alternatives to stationary source reductions and mitigation measures for increases in other pollutants as a result of RECLAIM SO_x shave. 2-3

WSPA recommends that a full Program Environmental Assessment be completed in order to capture all potential future projects that must be implemented as a result of this rule amendment. While a more simplified project EA may be desired, WSPA believes that, due to the complex and over lapping nature of these RECLAIM amendments, the full impacts of the amendments cannot be determined unless all future projects are examined. 2-4

WSPA offers these additional topic specific comments to be consideration in the EA:

AESTHETICS

WSPA concurs that the stacks that must be installed for the wet scrubber technology and the resultant plumes, both steam and SO_3, have the potential to create significant aesthetic impacts. WSPA believes that the District should conduct plume visibility analysis/modeling to adequately 2-5

address these impacts. "It should be noted that each refinery has multiple SRU trains that may each require separate wet gas scrubbers and stacks, resulting in multiple plumes for each facility." As previously stated, the District should insure that a thorough cumulative analysis should be conducted for this environmental area.

2-5 Cont'd

AIR QUALITY ("AQ")

WSPA believes that in order to employ some of the recommended technologies, it will be necessary to install additional NO_x emitting equipment to provide the heat and steam necessary for the operation of the SO_x control equipment. As such, the consideration of NO_x related AQ impacts should also be considered in the EA.

2-6

The EA should analyze whether the additional NO_x, PM_{10}, $PM_{2.5}$, CO, and GHG sources that must be installed for the purpose of implementing this project is consistent with the Basin's air quality goals. This project is heavily energy intensive and will result in large amounts of additional GHG emissions, possibly exceeding the District's significance threshold for industrial sources and conflicting with the goals of AB 32. Thus, this project may result in the diminishment of an existing air quality rule or future compliance requirement.

2-7

Additionally, in some instances the designated control equipment and the associated blowers can be maintenance intensive which could result in more shutdowns and start-ups at the facilities for the additional maintenance, resulting in additional flaring. This impact should be properly analyzed in the EA.

2-8

The Initial Study indicates that sensitive receptors may be exposed to substantial pollutant concentrations. WSPA encourages the District to conduct a Health Risk Assessment in order to adequately analyze these impacts.

2-9

HYDROLOGY AND WATER QUALITY

The third-party consultant reports upon which District staff primarily relies for technology recommendations and establishing BARCT levels outline the tremendous potential water use impacts associated with employment of "gas scrubbing" technologies. It should be noted that these water consumption impacts are associated with all three scrubber technologies, not just the wet-gas scrubbers.

2-10

Water Impacts Analysis

Table EX-3, module 3a includes the following water demand assumptions for wet/dry scrubbing technology for refinery fluid catalytic cracking units ("FCCUs"), refinery boilers/heaters, and refinery sulfur recovery units ("SRUs") and tail gas treatment processes :

> Fresh water – Between 1 and 90 million gallons per year for each scrubber.
> Waste water – Between 1 and 40 million gallons per year for each scrubber.

WSPA recommends that, due to the large size of scrubbers involved, the District should assume demand will be at the top end of the stated ranges. This is almost certainly true for NWGSs on FCCUs. Utilizing this assumption, the total impact would be a potential new demand for fresh water as high as one billion gallons per year (90 million gallons at 12 installations). Further, the Metropolitan Water District has implemented a Water Supply Allocation Plan which initiated mandatory conservation throughout Southern California, effective July 1, 2009. Thus, the District needs to carefully analyze whether enough raw water exists to meet these control equipment demands. 2-11

The increase in water usage can also result in an increased wastewater load on Publicly Owned Treatment Plants ("POTWs") as high as 440 million gallons per year (40 million gallons per each of an assumed eleven systems that would discharge to a POTW). Also, the implementation of this project may require additional paving at existing facilities thus creating more impervious surfaces, which can in turn result in additional storm water runoff that will require additional treatment. The potential for individual facility expansion or necessitated improvements to manage the significant increase in wastewater generation from the new emission reduction equipment may have a significant impact on local water treatment facilities that may not have the capacity to handle the additional demand. Additional wastewater capacity may need to be added as a result of this rule amendment. Also, the refineries currently have permitted discharge limits which may not be increased, unless and until treatment capacity is sufficient to handle wastewater demands. This should be closely analyzed in the EA. 2-12

These are dramatic resource consumption and waste figures and these considerations have clearly not been adequately addressed in the District's BARCT recommendations. WSPA strongly suggests that the EA conduct a thorough and multi-faceted analysis of all potential multi-media impacts associated with the current technologies employment. 2-13

Considering the water-intensive nature of some recommended technologies, WSPA suggests that great care be taken in conducting the environmental analysis and associated impacts to all recommended emission reduction technologies. 2-14

HAZARDS AND HAZARDOUS WASTE MATERIALS

The Initial Study identifies that there are potentially significant impacts in the area of hazards and hazardous waste materials. WSPA concurs and encourages the District to conduct a risk of upset analysis in order to adequately analyze the impacts in this environmental area. 2-15

ENERGY

The implementation of the recommended emission reduction technologies will impact all WSPA members and may require significant electrical and natural gas infrastructure improvements to accommodate the energy demands of the new equipment. WSPA has contended that a serious deficiency in the analysis of the full associated costs to employ these technology options exists in the consultant reports and now in the SCAQMD's staff reports. This should be corrected and fully analyzed in the EA. 2-16

TRANSPORTATION/TRAFFIC

While this resource area is identified as having potentially significant impacts, the Initial Study indicates that operation-related traffic is expected to be less than significant. WSPA believes that the District has not adequately assessed the number of supply delivery and waste disposal related truck trips that will occur as a result of this project. The EA should also consider a potential for significant cumulative impacts of construction projects at all SOx RECLAIM facilities and other projects. Construction activities may occur during the same time period as SOx RECLAIM facilities are facing the same compliance deadline. Total length of construction period may span over several years as several SOx sources within each facility are identified for reductions. Such long construction period may have some impact on aesthetics in the community. Given that much of this traffic increase will occur in the already heavily impacted port areas, WSPA believes the District should re-assess this area of potential environmental impact. 2-17

AREAS NOT IDENTIFIED AS SIGNIFICANT

The District has identified three additional environmental areas in which it has determined impacts will not reach significance: noise, land use and planning and solid/hazardous waste. WSPA believes that the potential exists for impacts in these areas to be significant and that the District needs to conduct a more robust analysis before making a determination of non-significance. 2-18

Noise

While the project will be introduced into industrialized areas that may already have high background levels, the District should more carefully examine the additional noise that will be 2-19

generated by the large blowers and other rotating equipment that are necessary to implement the control technologies identified.

2-19 Cont'd

Land Use and Planning

The equipment necessary to meet the proposed reductions will have to be installed in facilities that are already space constrained. The implementation of this rule may require refineries that don't have sufficient footprints to acquire additional property on a permanent or temporary basis, to accommodate the control equipment or to utilize as lay-down areas. The District should consider the additional permitting approvals, or land use decisions that may have to be undertaken to install this equipment.

2-20

Solid/Hazardous Waste

The installation of control equipment may require the demolition and removal of existing buildings or old equipment at the refineries in order to have sufficient room to accommodate the controls. Additionally, spent catalyst or scrubber cake will need to be disposed of appropriately. The Initial Study cites the District's own AQMP in determining landfill capacity, and fails to identify the current demand on landfill capacity and projected growth as baseline, nor does it estimate available landfill capacity. The statements are conclusionary and not based on any analysis. WSPA believes that the District should obtain the necessary data and assess the impacts on this resource quantitatively in order to determine whether any significant impact will result from the implementation of this project. Lastly, the EA should consider a potential for an increase in the fire hazard due to the use of chemicals in the SOx control process and the use of NH4 to control NOx.

2-21

ALTERNATIVES

Given the economic impacts that can result from this action, a complete alternatives analysis should be conducted. This analysis must address at least the following elements:

1)Examine as one of its project alternatives the implementation of Control Measure #2007CMB-02 as written in the 2007 AQMP, thus obtaining SO_x reductions of 2.9 tons per day by compliance year 2014.

2) Prepare incremental cost-effectiveness evaluations for alternative emission control levels of 5ppmv, 10ppmv, 25ppmv and 50ppmv BARCT levels for Sulfur Recovery Units/Tail gas Units.

3)For FCCUs, prepare incremental cost-effectiveness evaluations for alternative emission control levels of 10, 20, and 25 ppmv.

2-22

CONCLUSION

The situation in California and the South Coast Air Basin has changed greatly from when this initial analysis was started early last year. The economic health of the entire state of California has rapidly deteriorated over the last year, along with a continuing regional drought which has recently prompted the implementation of mandatory water management and conservation plans for the basin.

2-23

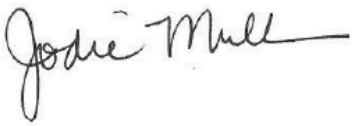
More now than ever a thorough and complete environmental analysis of projects within the basin with potential to have significant impacts to resources needs be conducted.

WSPA recommends that the District prepare an environmental document in the manner that will cover the worst case environmental analysis for all potential future projects resulting from this rule amendment. A Program EA should be prepared by the AQMD rather than a project EA. If the Program EA addresses the program's effects as specifically and as comprehensively as possible, many subsequent projects undertaken by refineries to comply with the rule could be found to be within the Program EA scope and additional environmental documents may not be required, or be required to a lesser degree (i.e. negative declaration vs. full EIR).

2-24

WSPA appreciates the District's consideration of these comments on the NOP/IS for Proposed Amended Regulation XX. Please feel free to call me or Steve Schuyler at (310) 408-2146 with any questions regarding these comments.

Sincerely,



Jodie Muller
Manager, External Affairs and South Coast Region
Western States Petroleum Association

Responses to Comment Letter #2
(Western States Petroleum Association, July 21, 2009)

2-1 The CEQA analysis in the PEA will focus on the following environmental topics: aesthetics, air quality, energy, hazards and hazardous materials, hydrology and water quality, and transportation. A cumulative impacts analysis for these environmental topics has also been included in the PEA.

2-2 The proposed project focuses on multiple source categories with varying SOx emission limits. The consultants prepared facility-specific reports to show all potential BARCT control options. As part of the rule development process, if a control option for a particular equipment/process at a facility was shown to exceed $50,000 per ton cost-effectiveness threshold, both costs and emission reductions anticipated by the installation of the control equipment was excluded from the analysis. For consistency with the proposed rule amendment and the BARCT analysis, the CEQA analysis in this PEA also excludes that equipment from the analysis. It is important to keep in mind, however, that the PEA not only analyzes the proposed project, but also analyzes alternatives. In any case, multiple control technologies are considered and evaluated and are not limited. Further, the control technologies with the worst-case environmental effects are included in the analysis.

2-3 Contrary to the comment, the permit moratorium[8] and availability of emission offset credits for non-RECLAIM pollutants have nothing to do with determining BARCT for sources covered under the proposed project, and overall environmental benefits and impacts of the proposed project. Only factors relevant to the proposed rule amendment should be included in the proposed project. As a reminder, Health and Safety Code §40406 defines BARCT as an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy and economic impacts by each class or category of source. The determination or establishment of BARCT does not need to take into account whether a not a permit can be issued pursuant to the permit moratorium. Lastly, because the proposed project calls for a reduction in SOx, a RECLAIM pollutant, emission offset credits for non-RECLAIM pollutants and their availability are not part of the proposed project and therefore, have not been included.

The PEA contains an elaborate analysis of all foreseeable environmental impacts that may result from implementing the proposed project and alternatives considered, but it is unclear what the commenter means by requesting the CEQA document to contain an analysis of "project constraints imposed by existing environmental laws and regulations, and project impacts on new laws that will become effective in 2010 and beyond." In accordance with CEQA Guidelines §15144 which requires an agency to use its best efforts to find out and disclose all that it reasonably can, if there is an existing environmental law or regulation that is germane to the proposed project, then a discussion is included in the PEA. However, to suggest that the PEA contain an analysis about how the proposed project will affect new laws that have not been promulgated yet is too speculative to evaluate since foreseeing the unforeseeable is not possible. Contrary to the comment, CEQA Guidelines §15145 allows an agency to terminate the discussion of an impact if the particular impact is determined to be too speculative for evaluation.

[8] Governor Schwarzenegger has signed Senate Bill 827 (Wright) which authorized the SCAQMD to begin issuing more than 1,200 air pollution permits frozen by a state court decision in November, 2008 (e.g., the permit moratorium) beginning January 1, 2010.

2-4 Pursuant to the SCAQMD's Certified Regulatory Program, an equivalent document called an Environmental Assessment is prepared in lieu of an EIR for rule projects. The Program EA (PEA) prepared for this proposed project is an amalgam of both a Project and Program EIR because the environmental effects of the project as a whole and on a detailed facility-specific basis are analyzed. Further, the PEA prepared for this proposed project can be relied upon for tiering purposes if future projects contain more detailed or varying facility-specific information when compared to the PEA prepared for this project.

2-5 SCAQMD staff disagrees with the commenter's suggestion that the District should conduct plume visibility analysis/modeling to address the aesthetics impacts from multiple WGS steam plumes because it is unnecessary. The available models for plume visibility analysis are applied when the composition of the plume is unknown. However, WGS technology has already been installed on one FCCU in the District and the unit produces a continuous plume that is made up of water vapor, and not SO3. An aesthetics analysis in the PEA has been prepared and it takes into account the potential installation of multiple scrubbers (and multiple plumes) at one facility. Refer to Chapter 4 of the PEA for this analysis.

2-6 The commenter does not elaborate as to what additional NOx emitting equipment would need to be installed or why it would be installed in order to provide heat and steam for operating SOx controls. However, the consultant reports take into account each individual facility's circumstances and have factored in the amount of energy and water (or steam), as well as other supplies such as caustic and catalyst, that may be necessary for operating each of the proposed SOx controls. This data was considered in the Air Quality analysis of the PEA.

2-7 The PEA takes into account the potential increases in criteria pollutants and GHGs that may result from implementing the proposed project and these increases are considered with the SCAQMD's air quality commitments in the AQMP.

While the proposed project may be perceived as energy intensive, as the commenter suggests, the analysis shows that the potential increased energy use does not exceed the CEQA significance thresholds for energy. Therefore, less than significant energy impacts are expected from the proposed project.

A GHG analysis was also conducted for the proposed project. On a facility-by-facility basis, the CEQA significance threshold of 10,000 MT per year for GHG emissions is not exceeded. However, when the GHG emissions from the entire project are considered together, the significance threshold is exceeded. However, the overall project will reduce SOx, a criteria air pollutant and a major precursor to PM10 and PM2.5, also criteria air pollutants. The residents of the South Coast Air Basin experience the worst PM2.5 exposure levels in the nation. As such, SCAQMD policy prioritizes the reduction in criteria pollutants in order to achieve the National and State Ambient Air Quality Standards.

The increase in GHG emissions that may result from installing SOx controls does not necessarily mean that there is a conflict with the goals of AB 32, because each affected facility will be required to reduce GHG emissions facility-wide in accordance with AB 32, regardless of whether or not the proposed project gets implemented. For facilities to

accomplish the goals of AB 32, older, less efficient equipment will likely need to be targeted in order to reduce their GHG emissions to 1990 levels.

2-8 The commenter's claim that flaring will increase if SOx control equipment will be installed because equipment such blowers are maintenance intensive is unsubstantiated. As a matter of conducting maintenance on support equipment such as blowers and pumps, engineering design typically builds in some redundancies (e.g., one main unit and one as a back-up) to maximize the time between turnarounds. In addition, turnarounds are a necessity of all equipment, not just control equipment. Further, paragraph (c)(3) of SCAQMD Rule 1118 – Control of Emissions From Refinery Flares, requires facility operators to submit to the Executive Officer an evaluation of options to reduce flaring during planned shutdowns, startups and turnarounds. Thus, for any SOx controls that are installed at any affected facility, this evaluation would need to be revised by each facility operator to accommodate the new equipment.

2-9 Chapter 4 of the PEA contains a health risk screening for NaOH. The analysis has demonstrated that the screening level of NaOH exposure to sensitive receptors will not be exceeded if WGSs using NaOH caustic are installed.

2-10 The water consumption estimates provided by the consultants, on which the PEA relies, show very conservative water demand estimates for various types of both wet and dry scrubbers.

2-11 Contrary to the suggestion, using the general ranges would grossly misrepresent the water demand and wastewater impacts, especially since a WGS has already been installed for a FCCU and the water use is far below the general ranges suggested. Instead, the consultants' reports identified the type of scrubber technologies that would be appropriate for each source at each facility and the reports include the corresponding, conservative water demand and wastewater generation estimates. These specific values, instead of the commenter's stated ranges, were relied upon to conduct the hydrology and water demand analysis in the PEA.

The PEA contains an extensive hydrology and water demand analysis as required by CEQA; it also takes into account the fact that California is in a State of Emergency for Drought and that water supply agencies, including the MWD, need to implement multi-layered potable water conservation efforts. A key factor as to whether there is enough water to supply the potential water demand for the proposed project is based on the type of water that would be needed. The commenter incorrectly implies that only raw (i.e., potable) water would be utilized to satisfy the potential total water demand of the proposed project, when, in actuality, WGS technology does not require potable water, and instead can function with recycled water or industrial use groundwater. Thus, the question that is addressed in the PEA is not only if there is enough total water for the proposed project, but what types of water can be supplied (i.e., such as the availability of recycled water to the affected facilities). SCAQMD staff has been working closely with staff from multiple water supply agencies to determine if there is sufficient total water supply (e.g., potable, recycled, and groundwater) available for the proposed project. All of the agencies contacted indicated that there will be enough water available to supply the potential water demand to all of the affected facilities, with the majority of the water supplied being recycled water, by the time the new WGSs come online. Only three facilities (Facilities G,

H and I) are expected to utilize potable water to implement the proposed project and one facility (Facility K) is expected to utilize industrial-use (non-potable) groundwater. For the full analysis, the commenter is referred to the Hydrology and Water Quality discussion in Chapter 4 of the PEA. See also the response to Comment 1-14.

2-12 As mentioned in Response to Comment 2-11, using the general wastewater ranges would grossly misrepresent the wastewater impacts. Instead, the consultants' reports identified the type of scrubber technologies that would be appropriate for each source at each facility and the reports include the corresponding, conservative wastewater generation estimates. These specific values, instead of the commenter's stated ranges, were relied upon to conduct the wastewater analysis in the PEA. Tables 4-41 and 4-42 in Chapter 4 of the Draft PEA summarize the potential wastewater impacts, and the estimated discharges for the entire proposed project is 270,532 gallons per day or 99 million gallons per year under Option 1 and 158,203 gallons per day or 58 million gallons per year under Option 2, not 440 million gallons per year as suggested by the commenter. Further, on a facility-by facility basis, the proposed increase in wastewater generation is not expected to exceed the wastewater CEQA significance threshold (a 25 percent increase in discharge from permitted levels) that would need to occur in order to trigger a wastewater permit revision. Therefore, because each facility has been shown to have the additional capacity to accommodate the proposed project, contrary to the comment, individual facility expansion or improvement of their existing wastewater treatment systems is not expected.

Regarding paving and stormwater runoff, contrary to the comment, typically most of the areas likely to be affected by the proposed project are currently paved and are expected to remain paved. Any new units constructed will be curbed and the existing units will remain curbed to contain any runoff. Any runoff occurring will continue to be handled by each affected facility's wastewater system and sent to an on-site wastewater treatment system prior to discharge. The surface water runoff is expected to be handled with each facility's current wastewater collection or treatment system. Storm water runoff will be collected and discharged in accordance with each facility's discharge permit terms and conditions.

2-13 The consultants and SCAQMD staff followed the BARCT selection process outlined in Part III of the Staff Report. The BARCT selection process includes five steps: 1) identify technology that can achieve maximum degree of reduction, 2) evaluate control effectiveness, 3) conduct a top-down cost analysis, 4) conduct an impact analysis for environment, energy and economic, and 5) select BARCT. Vendor guarantees are important information for Step 2. In evaluating the consultants' recommendation for BARCT and arriving at the SCAQMD's proposal for BARCT, in addition to vendor guarantees, SCAQMD staff relied on source test data, CEMS data, permitting data, and engineering evaluation. SCAQMD staff believes that adequate information has been provided to substantiate the proposed BARCT for all source categories. Recognizing that the proposed project involves resource-intensive control technologies, SCAQMD staff has prepared this PEA (as part of Step 4) to fully disclose the potential resource consumption and waste impacts associated with the proposed project.

2-14 See the response to Comment 1-19.

2-15 The hazards and hazardous materials analysis shows that there is only one substance that will have an increased in use and is considered a hazardous material subject to CalARP,

NaOH, as part of the proposed project. However, because NaOH has such a low vapor pressure (6.33 mm Hg at 40 ^{o}C or 104 ^{o}F) when compared to water (55.3 mm Hg at 40 ^{o}C 104 ^{o}F) at the same temperature, any spill of NaOH would not be expected to evaporate faster than water. Thus any spill of NaOH would be expected to stay in liquid form and would not likely exceed the ERPG-2 vapor concentration of five milligrams per cubic meter for NaOH. Further, operators at each affected facility who construct a new NaOH storage tank will need to build a containment berm large enough to hold 110 percent of the tank capacity in the event of an accidental release due to tank rupture. Thus, any spill of NaOH would not be expected to migrate beyond the boundaries of the berm on-site. Thus, any spill of NaOH is not expected to present a potential offsite public and sensitive receptor exposure. Lastly, since NaOH is not a flammable compound, other types of heat-related hazard impacts such as fires, explosions, boiling liquid – expanding vapor explosion (BLEVE) are not expected to occur. Thus, the hazards and hazardous materials impacts due to the use, tank rupture and the accidental release of NaOH will be less than significant for the proposed project.

2-16 Regarding the alleged necessity for infrastructure improvements, see the response to Comment 1-9. With regard to the alleged cost deficiencies, the commenter did not elaborate. Nonetheless, the consultants' reports contain an extensive facility- and unit-specific cost analysis. A contingency factor has been added to cover miscellaneous costs. This procedure is common to all cost estimates. Whether or not there is a dispute about the cost analysis in the consultant reports or staff report, the CEQA analysis in the PEA is not based on cost but instead is based on the consultants' energy demand estimates for electricity and natural gas, as well as the construction scenario estimates for gasoline and diesel fuel use. Refer to Appendix B of the PEA for the energy assumptions and calculations for both construction and operation activities.

2-17 In order to conduct the air quality analysis and estimate the amount of air emissions that would be generated from supply deliveries and waste disposal trips, supplies delivery and waste disposal data during operations was taken from the consultants' reports and applied to estimate not only the number of truck trips for the transportation analysis but the amount of diesel fuel needed for the energy analysis. The analysis in the PEA re-affirms the less-than-significant determination in the NOP/IS for operational-related traffic. Thus, there is no need to re-assess this portion of the PEA. Refer to Appendix B of the PEA for the assumptions and calculations.

As for cumulative impacts, the PEA considers the impacts of construction activities at all of the affected SOx RECLAIM facilities. The analysis takes into account overlapping construction activities at multiple facilities (the overlapping of four WGS installations) over a seven-year period and a lengthy (18-month) construction period per WGS installed. The PEA, does not, however, include the cumulative effects of other future construction projects outside of the SOx RECLAIM project because the construction of future projects is unknown at this time and inclusion in the PEA would be speculative at best.

With regard to construction activities and aesthetics impacts, Chapter 4 of the PEA includes an aesthetics analysis for both construction and operation of the SOx control technologies.

2-18 The analysis in the PEA confirms that there will be less than significant impacts for noise, land use and planning, and solid/hazardous waste. Detailed responses to this comment can

be found in the following responses: 1) response to Comment 2-19 addresses noise impacts; 2) response to Comment 2-20 addresses land use and planning impacts; and, 3) response to Comment 2-21 addresses solid/hazardous waste impacts.

2-19 The proposed project is expected to involve the installation of large, industrial equipment with the potential to generate noise. Nonetheless, the construction and operation activities associated with the proposed project will take place at existing facilities that are located in industrial, heavy manufacturing settings with an existing noise environment dominated by noise from existing equipment onsite, vehicular traffic around the facilities, and trucks entering and exiting each facility premises. Because of the existing noise setting, any additional noise from the proposed project is not expected to produce noise in excess of current operations at each of the existing facilities at the property line. So, if SOx control equipment is installed, the operations phase of the proposed project may add new permanent sources of noise to each affected facility. However, it is expected that each facility affected will comply with all existing noise control laws or ordinances. Further, OSHA and Cal/OSHA have established noise standards to protect worker health. These potential noise increases are expected within the allowable noise levels established by the local noise ordinances for industrial areas, and thus are expected to be less than significant.

2-20 Plot space concerns were addressed in the consultants' report, section H:

"Wet gas scrubber equipment footprints and space requirements for the FCCUs and the SRU/TGTUs are shown in the confidential appendices for each refinery where measures have been selected. These specifications have been compared with the plot plans provided by the respective refineries, and where applicable, are presented in the costing workbooks."

Further, Tables 4-36 and 4-37 in the Draft PEA contains a summary of these plot space estimates on a facility-by-facility basis. If all affected facilities conduct site preparation activities, the total amount of disturbed area for all of the facilities combined is estimated to be 48,126 square feet or 1.1 acre under Option 1 and 40,976 square feet or 0.94 acre under Option 2. The consultants' reports did not indicate a need for any facility to acquire additional property to accommodate the proposed project. Thus, there is no need to consider additional permitting approvals or land use decisions relative to plot space in the PEA.

2-21 The construction portion of the air quality analysis in the PEA accounts for the potential to demolish existing buildings and foundations and dismantle existing equipment and the construction equipment that would be used for these activities as part of site preparation for installing SOx control equipment. While the NOP/IS acknowledges that there may be demolition wastes associated with these site preparation activities, any metals that are part of demolished equipment, piping or wiring, would be considered a commodity and thus would be sold as scrap for reuse or recycling. The remainder of demolition waste that cannot be recycled would be disposed of in a landfill. Estimating the scope of demolition waste that could be generated and sent to a landfill can be qualitatively determined relative to plot space needed to install the new SOx controls. As mentioned in the response to Comment 2-20, the amount of plot place that would be needed to construct the new SOx control equipment (i.e., the amount of space that would have demolition activities occur) is relatively small on a facility-by-facility basis, and is approximately one acre for the total

project. This implies that whatever existing buildings or equipment that is on the each facility's plot space falls is also relatively small, when compared to the total landfill capacity as discussed in the NOP/IS.

With regard to solid waste generation such as spent catalyst or scrubber cake, the commenter implies that these byproducts require disposal. On the contrary, each facility was surveyed about how their current catalyst fines or other solid waste fines (e.g., ESP fines) are handled and because these byproducts are a commodity, the majority is recycled. Specifically, of the 11 facilities, nine facilities have their catalyst fines picked up by a transport company that in turn trucks the spent catalysts to a local cement manufacturer for recycling, two facilities (Facility B and Facility I) either truck their fines to a landfill or to a cement plant for recycling (depending on the silica, iron and other metals content in the spent catalyst), and one facility (Facility J) does not use catalyst or generate fines as part of its operations and is not expected to use any as part of implementing the proposed project. Based on the survey responses, even with a potential increase in solid waste of 11.75 tons per day that may result from the proposed project, the same facilities that currently recycle will be expected to continue to do so. For the two facilities that do not consistently recycle their catalyst fines (Facility B and Facility I), a maximum of 2.52 tons per day of solid waste may end up in a landfill from two of the 11 facilities provided that the composition is unsuitable for cement manufacturing. This amount is a conservative worst-case because the operator at Facility B has indicated that their catalyst fines are now being recycled because the composition has altered to be more suitable for cement manufacturing. If the composition of the spent catalyst from Facility B after implementing the proposed project remains suitable for cement manufacturing, then the additional 2.47 tons per day will also be recycled and only 0.05 tons per day or 100 pounds per day from Facility I would need to be trucked to a landfill as a result of the proposed project. For these reasons, the solid/hazardous waste generated from the proposed project are not are expected to exceed total landfill capacity.

For the hazards/hazardous materials analysis, a fire hazard analysis of the different materials being used (e.g. catalyst, caustic, et cetera) is included in Chapter 4 of the PEA. However, the fire hazard associated with the use of ammonium (NH4) to control NOx is not germane to the proposed project and as such, is not analyzed in the PEA.

2-22 As required by CEQA, the PEA includes an alternatives analysis and one of the alternatives (referred to herein as Alternative B) is the AQMP alternative, as suggested by the commenter. However, contrary to the comment, CEQA does not require an evaluation of cost-effectiveness. Thus, a cost-effectiveness analysis for varying BARCT levels for SRU/TGUs and FCCUs will not be included in the PEA. However, for the proposed project, facilities for which the cost-effectiveness of a particular control technology exceeded $50,000 per ton reduced were assumed not to use that control technology. Instead, the PEA contains alternatives that analyze varying compliance levels for the affected source categories. This analysis can be found in Chapter 5 of the PEA.

2-23 The purpose of CEQA is to: 1) inform governmental decision-makers and the public about potential environmental effects of a project; 2) identify ways to reduce adverse impacts; 3) offer alternatives to the project; and, 4) disclose to the public why a project was approved. In compliance with CEQA, this PEA has been prepared to thoroughly analyze the environmental effects (benefits and impacts) of the proposed project. As part of this

analysis, the PEA takes into account California's State of Emergency for Drought in the Hydrology and Water Quality existing setting discussion in Chapter 3 and analysis in Chapter 4.

The PEA does not consider the economic health of California, as that issue not part of the project. Further, by the time this project is implemented, the economic health of California could substantially change, making the point moot. The cost of the proposed project will be considered in the socioeconomic analysis. While CEQA Guidelines §15131 (a) allows, but does not require, the economic effects of a project to be included in the CEQA document, the economic effects shall not be treated as significant effects on the environment and the focus of the analysis shall be on the physical changes. This PEA shows that the proposed project contains significant adverse impacts as well as benefits and focuses on the physical effects of the proposed project.

2-24 See the response to Comment 2-4.

Diamond Bar, CA 91765-4178

Re: Comments on Notice of Preparation of a Draft Environmental Assessment and Initial Study for Proposed Amended Regulation XX

Dear Ms. Radlein:

Rhodia Inc. appreciates the opportunity to provide comments on the South Coast Air Quality Management District's Notice of Preparation of a Draft Environmental Assessment and Initial Study for Proposed Amended Regulation XX (NOP/IS). Because these comments contain confidential business information, we request that the District treat the entirety of these comments as business confidential and protect them from public disclosure. These comments should be distributed only to those District personnel with a need to know this information in the context of the review and revision of the NOP/IS. 3-1

Rhodia previously has provided comments to the District on the proposed amendments to Regulation XX, most recently relating to the draft Staff Report for those proposed amendments. Rhodia incorporates those previous comments by reference here. 3-2

As you know, the District's proposed amendments to the SOx RECLAIM rules (Regulation XX) rely on a reassessment of the Best Available Retrofit Control Technology (BARCT) level for major SOx RECLAIM sources, as proposed in Control Measure CMB-02 in the District's 2007 Air Quality Management Plan (AQMP). Though Control Measure CMB-02 is a SOx control measure, the District has communicated that it seeks these additional SOx reductions as a strategy for meeting the National Ambient Air Quality Standards (NAAQS) for fine particulate matter (PM2.5) by 2015. 3-3

Both the California Environmental Quality Act (CEQA) and District Rule 110 require, among other things, that the District to identify all potential adverse environmental 3-4

bingham.com

impacts of the proposed rule amendments, and to identify and implement alternatives or mitigation measures to those amendments. In preparing the draft Environmental Assessment (EA) for the proposed rule amendments, District staff should ensure that it considers a number of impacts and alternatives: 3-4 Cont'd

- State law prohibits the District from setting BARCT levels without considering the relative environmental and economic impacts on each affected source category. To date, the District's proposed regulations (which the District estimates would cost all stakeholders over $1 billion to meet) do not reflect a full and fair consideration of lower cost SOx control alternatives that would still allow the District to accomplish its objectives of reducing PM10 and PM2.5 to meet the NAAQS. In preparing the EA, District Staff must consider and evaluate (1) the relative environmental and economic impacts of requiring the proposed SOx controls for sulfuric acid manufacturing instead of requiring greater reductions from different industrial sectors, and/or from direct sources of PM2.5 and/or PM10 throughout the Basin; (2) the relative environmental and economic impacts of obtaining SOx reductions through alternative, less expensive control measures (such as use of cesium catalyst) within the sulfuric acid manufacturing industry; (3) the prospect that the proposed regulations will result in crippling spikes in SOx RECLAIM credit prices and/or a general scarcity in credits, and the relative environmental and economic impacts likely to be associated with such a crippling of the SOx RECLAIM market. 3-5

- District Staff also must consider and evaluate the amount emissions produced from energy used to produce caustic required for wet scrubbers to be used in the sulfuric acid manufacturing industry, and the emissions from transporting caustic to the facility. 3-6

- Staff currently is using 2005 emissions inventories as the baseline against which to measure anticipated emissions reductions from the proposed amendments. Staff must take into account any SOx emissions reductions and control measures that have been put into place since that time, and discount the District's estimated emissions savings figures appropriately to determine the true cost-per-ton cost effectiveness of the proposed amendments and any feasible alternatives. 3-7

- Both the District and stakeholders have acknowledged that the proposed regulations would involve significant compliance costs for the refining industry, and could result in increases in the price of gasoline in Southern California. Staff must consider the full range of potential impacts Basinwide that could result from such higher gasoline prices. 3-8

- Despite optimistic estimates from District Staff to date, stakeholders have explained that installing actual emissions controls likely will take longer that the District anticipates. Emissions reductions from new control equipment may not be available to assist in PM2.5 attainment in the District until 2012 or later, 3-9

depending on when the District approves the BARCT revision. Accordingly, District Staff must consider and evaluate the impacts of requiring SO2 emissions reductions that would not yield PM2.5 reductions until 2012 or later, and whether less-costly alternatives may be available to achieve PM.5 and/or SOx reductions on a faster schedule.

3-9 Cont'd

These are only some of the additional factors District Staff should consider in preparing the draft EA. The proposed amendments would result in unprecedented compliance costs across a host of industries, during the most severe economic downturn the nation has seen in over 75 years, and during a time when the availability of capital funding is extremely limited. The District's EA must take into account all of the environmental and economic impacts that are likely to flow from the adoption of the proposed regulations during this unique confluence of events.

3-10

As always, please feel free to contact us if you have any questions

Very truly yours,

Michael S. McDonough

Responses to Comment Letter #3
(Bingham McCutchen LLP, July 21, 2009)

3-1 Contrary to the original comment, Bingham representative Michael S. McDonough has consented to have the comments and responses to their letter included in the Draft PEA per the following email:

Subject: Comments on Notice of Preparation of Environmental Assessment and Initial Study for SOx RECLAIM Amendments

Ms. Fernandez -

Thanks for your voice mail last week. This e-mail is to confirm that, notwithstanding the confidentiality label on Rhodia's July 21, 2009 comments on the SCAQMD's Notice of Preparation of Environmental Assessment and Initial Study for the proposed SOx RECLAIM amendments, we consent to have the comments and the SCAQMD response(s) published in the CEQA document appendix for the proposed amendments. If you have any questions, please feel free to call me. Thank you.

3-2 Two comment letters from Rhodia regarding the proposed amendments and staff report were received on April 29, 2008 and November 25, 2008. As none of the comments in these letters pertain to CEQA or the CEQA analysis for the proposed project, they are not repeated here. Instead, responses to these comments can be found in Part 1 of the SOx RECLAIM Draft Staff Report – BARCT Assessment & RTC Reductions Analysis, Chapter 14, December 2009.

3-3 In the *Clean Air Fine Particle Implementation Rule*, the USEPA specifically requires the non-attainment areas (which includes the SCAQMD) to evaluate all control measures to reduce direct PM2.5 emissions, as well as PM2.5 precursors, especially SOx. It should be noted that the 17 million residents of the South Coast Air Basin experience the worst PM2.5 exposure in the nation. While the 2007 AQMP lays out a multi-pollutant control strategy to demonstrate attainment with the federal PM2.5 standards, it identifies NOx and SOx reductions by far as the two most effective tools in reaching attainment with the PM2.5 standards. Because sulfur dioxide (SO2) is a PM2.5 precursor, SO2 reductions that may occur as a result of the proposed project will have the effect of indirectly reducing PM2.5 and contribute to the federal PM2.5 attainment demonstration.

3-4 The CEQA analysis in the PEA will focus on the following environmental topics: aesthetics, air quality, energy, hazards and hazardous materials, hydrology and water quality, and transportation. For any topics that have been shown to have significant impacts, a cumulative impacts analysis for these environmental topics and an alternatives analysis will also be included in the PEA.

3-5 As mentioned in the response to Comment 3-4, the PEA will contain an alternatives analysis and each alternative may have varying economic impacts. The alternatives analysis in the PEA will explore various configurations of SOx control options and each alternative's environmental impacts. As for cost, the cost-effectiveness of the rule and the alternatives can be found in can be found in Part 1 of the SOx RECLAIM Draft Staff Report – BARCT Assessment & RTC Reductions Analysis, Chapter 14, December 2009. In addition, the socioeconomic impacts of the rule and the alternatives will be analyzed in a separate report from the PEA.

3-6 As part of installing a WGS on a sulfuric acid plant, the consultants' reports show that sodium hydroxide (NaOH) caustic will be needed to operate the WGS. NaOH will also be needed to operate WGSs for other equipment source categories. The air quality discussion and the energy discussion in Chapter 4 of the PEA take into account the air emissions that may be generated and the fuel needed for multiple truck deliveries of the caustic solution to all of the affected facilities, including the sulfuric acid plant. With regard to the comment about the increased electricity needed to produce caustic, the PEA assumes that because caustic is produced locally, it is locally available for transport and it is likely that the existing local caustic manufacturers can handle the proposed increase in caustic for the entire project. The energy analysis in Chapter 4 of the PEA takes into account the additional energy that would be needed for local caustic manufacturers to make enough extra caustic to satisfy the total caustic demand of the proposed project (i.e., 13.24 tons per day under Option 1 and 8.79 tons per day under Option 2).

3-7 Very little SOx emission reductions were projected in the 2003 AQMP. The most substantial amount of SOx reductions resulted from the November 2005 amendments to SCAQMD Rule 1118 – Control of Emissions From Refinery Flares, which implemented stationary source control measure CMB-07: Emission Reductions from Petroleum Refinery Flares (2003 AQMP), to reduce SOx emissions by 2.1 tons per day. Subsequent to amending Rule 1118, the 2007 AQMP was adopted and it calls for significant reductions of SOx from both stationary and mobile sources by 2014. Regional modeling in the 2007 AQMP indicates that an overall emission reduction of 24 tons per day of SOx is needed to meet the particulate standard in 2014. Of the 24 tons per day reduction, mobile source control measures from CARB and the District can potentially reduce 21 tons per day. The remaining three tons per day of SOx reductions can come from the stationary source control measure for RECLAIM facilities. However, it should be noted that additional reductions of SOx and NOx emissions will be needed to meet the 24-hour federal PM2.5 standard. A BARCT reassessment for SOx is therefore essential to identify the potential sources that can generate three tons per day of SOx reductions required for 2014.

3-8 SCAQMD staff is in the process of conducting a socioeconomic analysis for the proposed amendments to the SOx RECLAIM program. This analysis will include annual costs of

compliance and the resulting macroeconomic impacts on the Basin's economy. The analysis will also include potential impacts on gasoline prices in the Basin.

3-9 Given the amount of lead time needed for engineering design, planning and financing, the anticipated construction date assumed in the PEA is 2012 at the earliest, spanning over a seven-year period, and with construction completed and units operational by January 1, 2019.

3-10 With regard to compliance costs, refer to the response to Comment 3-8. SCAQMD staff will also assess funding availability to the affected facilities regarding their compliance with the proposed amendments.

Subject: Re-submittal of Environ data: April 15

<<SOx RECLAIM April 15 trans note socioecon 09132010.doc>> <<SOx to SCAQMD 04152010A.ppt>>

All: This email and attachments are follow-up to your SOX RECLAIM Working Group meeting and Public Consultation meetings held on September 8. As you will recall, at those meetings, we discussed the need for the District to include, within the Socioeconomic Report, information on compliance costs resulting from the District's original proposal of a 64% reduction in RTCs. During those conversations, it became clear that some of you working on the RECLAIM project may not have been aware of the information we had provided to the District earlier this year. To address this omission, the Environ presentation that we originally submitted to the District on April 15 is again attached for your review and as input to the Socioeconomic Report.

Also, as my note to you suggests, we will soon provide you with additional information on impacts to the petroleum industry and the regional economy. This new information builds upon, and in some cases updates, data included in the April 15 presentation. I hope to schedule a meeting to brief you on this new information in the near future.

Thank you.

Re: Transmittal of Costs to Refinery Operations: Input to Socioeconomic Report and Initial Response to Draft Programmatic Environmental Assessment

Dear Mr. Dabirian and Ms. Radlein,

In our conversations during the SOx Working Group meeting and the Public Consultation Meeting Regarding Proposed Regulation XX – SOx RECLAIM, you requested that we send you the cost data we already provided to the District on April 15.

We are pleased that the District remains interested in understanding the extraordinary costs to the refining industry to comply with the proposed shave, and the potential impacts on the region. However, we are disappointed to see that the data we provided on April 15 was not included in the DPEA. Apparently it also has not been included in the initial socioeconomic analysis. 1-1

To rectify this omission, and to ensure that data from the affected industry is included in the Final Programmatic Environmental Assessment and in the Socioeconomic Report, we have attached the April 15 presentation that was provided to the District.

We are also finalizing our analysis of the possible economic impact of these costs on the petroleum and the region. Upon completion of that work, we will share our findings with you.

If you have any questions, please contact me.

Sincerely,

970 W. 190th Street, Suite 770, Torrance, California 90502

WSPA RECLAIM Cost Estimate

- Objective was to estimate, using confidential company data, costs to comply with 25% and 60% shave in RTC Allocations
- WSPA retained ENVIRON to collect data and perform analysis with the results aggregated and de-identified

1

Survey Methodology

- Companies submitted operating and capital cost estimates to ENVIRON
- Company data included, for example:
  - Modifications to FCCU, SRU/TGU
  - Facility/Process improvements including changes in facility operations that were not associated with FCCU or SRU/TGU such as improved monitoring equipment

2

Survey Methodology (Cont'd)

- Survey Time period: September 2009 – November, 2009.
  - ENVIRON followed up with companies, as appropriate, to verify that the data was submitted on a consistent basis
  - Follow up by ENVIRON and WSPA continues
  - Confidentiality of data continues to be protected

3

Example Cost Calculation

- Costs are Net Present Value of capital and operating costs at 4% for 25 years
  - Tried to emulate method used by the SCAQMD staff.
  - Cost Effectiveness is NPV/emissions reduced over project life.
  - Emissions based on 2005 year

Responses to Comment Letter #1
(Western States Petroleum Association, September 13, 2010)

1-1 The commenter has suggested that the PEA should include the submitted cost data as part of the CEQA analysis. However, the comment letter does not raise the potential for any physical changes to the environment which needs to be addressed through CEQA. Under CEQA Guidelines §15131(a), the economic effects of a project shall not be treated as significant effects on the environment. An environmental document may trace a chain of cause and effect from a proposed decision through economic effects to physical changes caused by economic effects. This comment does not contend that the purported economic effects will result in any physical changes. As a result, the focus of the analysis was on the physical changes caused by the proposed project.

CEQA does require public agencies to consider economic and social factors together with technological and environmental factors in deciding whether changes in a project are feasible to reduce or avoid the significant effects on the environment identified in the CEQA document. However, this information need not be presented in the CEQA document itself (CEQA Guidelines §15131(c)). Moreover, the comment does not contend that the project will result in significant adverse environmental impacts.

The SCAQMD presents information related to the economic impacts of the project in the socioeconomic analysis. As such, the Governing Board will be presented with both the PEA and the socioeconomic analysis to consider when reaching a decision on the proposed project.

Subject: FW: Draft Comment Letter PEA Reg XX 09292010(V2)

Bill,
Per our call, attached is another copy of Owens' comment letter on the Reg.XX Reclaim SOx "shave rule".
I understand Ev Ashworth earlier forwarded you a copy of this but his e-mail contained a boilerplate confidentiality provision(as mine probably does below as well) and there was concern at the District whether you could publish the comment letter. This will confirm that you can ignore that confidentiality paragraph on Ev's email(and mine here).
He submitted the letter on behalf of Owens to be published in the public record(as do I).
I also understand Ev messengered hard copies of the Owens letter out to the District for filing as well.
Owens will be setting up a mtg with District to discuss the shave very soon. Thanks fro calling me to clear away any confusion Electronics!
Thanks

Ms. Radlein:

Attached, please find digital copies of the comments provided by the Owens Brockway Vernon California container glass manufacturing facility on the District's Draft Program Environmental Assessment regarding the proposed amendments to Regulation XX-RELCAIM (Rule 2002; the proposed SOx shave). A hard copy, which is addressed to you, will be hand delivered to the front desk later today (probably by mid-afternoon).

If you would, may I ask that you confirm receipt of these digital comments?

Thank you; I would welcome a call should you have questions, etc.

Regards, Ev Ashworth

Re: Proposed Amended Regulation XX –Comments on the Program Environmental Assessment - Owens-Brockway Glass Container Inc. Vernon Facility (SCAQMD ID 7427)

Dear Ms. Radlein:

By this letter, Owens-Brockway Glass Container Inc. Vernon, California facility (Owens Vernon facility) provides its comments on the August 2010 Draft Program Environmental Assessment (DPEA) that the District prepared to consider the impacts of the proposed amendments to Regulation XX, Rule 2002. Specifically, we provide to the District additional technical information that should be considered under the California Environmental Quality Act (CEQA) by the District's decision makers in setting Best Available Retrofit Control Technology (BARCT) for glass manufacturing. As summarized in correspondence previously submitted to the District, the Owens Vernon facility has already installed BARCT, which the District has recognized as Best Available Control Technology for the control of sulfur oxides[1]. Further, there is no example of a glass container manufacturing facility with a control configuration as suggested by the District to represent BARCT. Therefore, it is especially important for the District's CEQA to fully disclose the potential impacts of the proposed BARCT for container glass manufacturing – a technology that has not worked when previously applied by glass manufacturing operations here in Los Angeles

2-1

Background on Owens Vernon Facility

To put these technical issues in perspective, it is helpful to have an understanding of our plant's customers, employees, and our facility's role in sustainable manufacturing resources in the Los Angeles area. The Owens Vernon facility has been in business for over 70 years. Over the past 25 years, some six individual glass container manufacturing facilities have ceased to operate in

2-2

[1] See attached September 22, 2010 comments filed by the Owens Vernon facility with the District.

the Los Angeles basin, such that the Owens Vernon facility is the only remaining container glass manufacturing facility located within the District. We produce between 2 and 3 million glass bottles per day on five production lines pulling from two furnaces and purchase approximately 330 tons/day of recycled glass. We have 260 employees that represent 15 different countries and territories of origin, over one third of whom have worked at the Owens Vernon facility for over 20 years. The average salary for Owens Vernon staff is three times the minimum wage, with medical, dental and pension plan benefits. Our customers are here in Los Angeles; over 75% of our shipments are to customers within 25 miles of the of the Owens Vernon plant. Thus, the Owens Vernon Facility plays a vital role in maintaining sustainable container glass manufacturing in the Los Angeles area.

2-2 Cont'd

It is also important to put our environmental controls into proper perspective. Owens has been an innovator of emission controls on glass manufacturing. At significant cost, our company implemented oxygen-fuel fired glass manufacturing technology to reduce nitrogen oxide (NOx) emissions from high temperature furnace exhaust. This innovative process control technology was installed to comply with NOx RECLAIM allocations. To comply with SOx RECLAIM, Owens Vernon first employed a SOx control system that injected a water-based sorbent into the exhaust stream prior to the existing electrostatic precipitators (ESPs). However, our facility experienced numerous problems with this technology [*Petition for an Ex Parte, Emergency, and a Short Variance*, Case No. 4472-9, Facility ID 007427, May 15, 1997, paragraphs 6-10]. We also note that the Ball-Foster El Monte facility experienced significant operating problems with its wet scrubber technology, which resulted in the company's decision to replace the wet scrubber with a dry scrubber followed by an electrostatic precipitator [*Petition for Modification and Extension of a Variance*, Case No. 108-20, Facility ID 108701, April 9, 1997, paragraphs 6-14].

2-3

Therefore, with the District's approval, Owens Vernon selected dry scrubbing technology (Trona injection) to reduce sulfur dioxide to comply with RECLAIM. It is important to note that this dry scrubbing technology was identified by the District as Best Available Control Technology (BACT) for the control of sulfur oxides. The dry scrubber controls are followed by the existing three ESPs that operate in parallel to remove entrained Trona sorbent and particulate emissions from the exhaust of the two glass melting furnaces. These technologies reduce sulfur oxide emissions by up to 90%. It is critical to note that the Owens Vernon facility actual SOx emission rate (approximately 0.6 pounds/ton of glass pulled) is significantly lower than the permitted SOx emission rate established for the container glass manufacturing facility in Seattle, Washington that is controlled by the wet scrubber technology evaluated by the District in its BARCT determination.

2-4

Summary of Comments on DPEA

With this background, we now turn to consider technical issues that should be properly addressed by the District's DPEA and support the Rule 2002 revisions. In accordance with CEQA, and its Rule 110, the SCAQMD prepared a DPEA to analyze the environmental impacts of the proposed amended Regulation XX (the "Project"). As discussed below, the DPEA fails to comply with CEQA and the CEQA Guidelines (the "Guidelines") for several reasons.

As an overarching premise, an agency implementing a certified regulatory program must adhere to the basic policies and substantive obligations established by CEQA (see Guidelines §15250). Accordingly, an environmental document prepared pursuant to a certified regulatory program must include a description of the project, alternatives to the project, and mitigation measures to minimize any significant adverse environmental impacts (see Pub. Resource Code §21080.5(d)(3)(A)). In addition, public agencies should not approve projects as proposed if there are feasible alternatives or feasible mitigation measures available that would substantially lessen the significant environmental effects of the project (see Pub. Resource Code §21002). And, of course, the agency must support its analysis with substantial evidence. Here, the DPEA failed to meet several of these standards. 2-5

First, the DPEA's analysis of water supply is inadequate. The DPEA does not provide substantial evidence to factually demonstrate that adequate water supplies are available. The DPEA also acknowledges that there are no guarantees for substantial portions of the water supplies that it factored into the supply and demand analysis. In other words, the DPEA is not only relying on speculative water sources, but also relying on unsupported water supply claims. That is impermissible.

In addition, the DPEA's proposed water supply mitigation measures (i.e., HWQ-1 and HQW-2, use of recycle water) are inadequate because the measures do not minimize the water demand impacts of the Project. Also, the DPEA concludes that water demand impacts are significant, but then fails to propose all feasible mitigation measures. Worsening matters, the DPEA's cumulative impact analysis provides no meaningful assessment of the Project's cumulative water demand impacts. These are clear failures of CEQA requirements. 2-6

Second, the DPEA's analysis of greenhouse gas ("GHG") impacts is inadequate. The DPEA concedes that the Project will have a significant GHG impact. As noted above, that triggers the need to propose all feasible mitigation measures. The DPEA, however, only proposes GHG-1 and GHG-2 (i.e., use of recycle water, see p.4-31), which are inadequate from a CEQA perspective. 2-7

Third, the DPEA's analysis of alternatives is inadequate. Without the No Project Alternative, there are only two real alternatives, neither of which have a bearing on container glass 2-8

manufacturing. These two alternatives do not constitute a reasonable range under CEQA, especially considering the Project's wide-reaching effects on the industries subject to Regulation XX. SCAQMD must propose additional alternatives that are capable of reducing the Project's significant impacts.

2-8 Cont'd

Fourth, the DPEA improperly assumes that the Project will allow affected facilities to implement BARCT over a 9-year period, and that the peak construction emissions are expected to occur in 2012. This assumption is not supported with any technical analysis; rather the DPEA simply refers to the proposed compliance dates outlined in Rule 2002 (i.e., 2012-2019). Under CEQA, where specific data are not available, the responsible agency is to make reasonable worst case assumptions. Thus, absent any analysis, the peak construction should be assumed to occur in 2011, as facilities must comply with the SOx shave as of 2012. Further, in response to comments provided by the public, the DPEA assures decision makers that there is adequate production capacity to supply wet scrubber control technology to all affected sources within the seven year compliance period provided by Rule 2002 (See Comment 9, Table 1-1). We have been unable to find technical data in the DPEA to support this assumption. Therefore, consistent with CEQA guidelines, the analysis should be based on reasonable worst case assumptions, which would require that all affected facilities install controls within a two year period, not the seven year period suggested by the DPEA.

2-9

2-10

We provide additional technical data below indicating where impact analyses in the DPEA are deficient in the following areas:

- Aesthetics
- Air Quality
- Air Toxics
- Land Use
- Noise
- Water Demand
- Water Quality

Failure to remedy these deficiencies before approving the Project would be a prejudicial abuse of discretion. Therefore, we respectfully request that the SCAQMD resolve these and other CEQA deficiencies, so that the decision makers are properly informed before taking any action on the Project.

2-11

Aesthetics

In the analysis of Aesthetics impacts from project operation, the DPEA states on p. 4-8 the following:

2-12

- "If any WGS is installed as part of the proposed project ... at any of the affected facilities, the steam plume, though visible, is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant."

- "Further, the visual continuity of the surrounding area is not expected to be adversely impacted because each WGS, if constructed, will be built within the confines of industrial areas and would be visually consistent with the profiles of the existing affected facilities."

The Owens Vernon glass plant is different from some of the other facilities affected by the proposed rule in that there currently are no visible steam plumes at the facility or nearby. Therefore, the addition of a visible plume is not visually consistent with the profile of the existing facility. We also disagree that a scenic highway or corridor within the area of the melting plant is a prerequisite for a significantly adverse affect on aesthetics. It is common practice to address aesthetics impacts for a facility in an industrial area by taking photographs of the facility from various vantage points and superimposing a mockup of the potentially offending visual element (in this case, a steam plume) on each photograph. It is not acceptable to draw broad conclusions regarding an impact that was previously determined to be potentially significant in the NOP/IS without providing the decision makers the means to form their own judgment. We therefore request that the aesthetics section be revised to properly describe the impact of the proposed BARCT on the container glass sector to properly inform the District's decision makers on the visual impacts of the proposed BARCT.

2-12 Cont'd

Air Quality

The DPEA did not address what the effect would be on the impact of NOx emissions from the furnaces due to installation of wet gas scrubbers. The exhaust streams from the furnaces currently pass through dry gas scrubbers and electrostatic precipitators (DGS-ESP). Further treating by wet scrubbers would result in evaporative cooling of the exhaust. The cooler resulting plumes would have substantially less buoyancy and plume rise, and the ground-level concentrations of pollutants not affected by the WGS (such as NOx) would be higher. To get a sense of this effect, the EPA SCREEN3 dispersion model was used to quantify the potential increase in maximum one-hour average NOx concentration. The assumed stack parameters with and without the WGS cooling effect are shown in the table below:

2-13

Parameter	Without WGS*	With WGS
Exhaust Temperature (°F)	650	150

Parameter	Without WGS*	With WGS
Flow Rate (acfm)	30,000	30,000
Stack Height (ft)	80	80
Stack Diameter (ft)	3.5	3.5
Building Height (ft)	40	40
Building Length (ft)	150	150
Building Height (ft)	100	100

*DGS-ESP case

The only difference in the modeled parameters is the exhaust temperature. The exhaust temperature for the DGS-ESP case was approximated from source test data. The temperature for the WGS case was approximated from manufacturer's data. The stack height and diameter are the values for the current ESP stacks at the Owens Vernon facility. The building dimensions, however, are a very simplified representation.

In both cases, the SCREEN3 model was run with a NOx emission rate of 2.0 g/s, which equates to 380 lb/day, the approximate average daily NOx emission rate for the Owens Vernon facility.

2-13
Cont'd

The SCREEN3 results, which are shown in the attached output files, indicate that there is the potential for a substantial difference in predicted maximum one-hour average ground level concentration. The DGS-ESP case yielded a maximum NOx concentration of 30 $\mu g/m^3$ at 120 meters downwind, whereas the WGS case yielded a maximum NOx concentration of 50 $\mu g/m^3$ at 187 meters downwind.

These results are interpreted as follows. The federal one-hour average NO_2 standard established in April of this year by the EPA is 189 $\mu g/m^3$. The background NO_2 concentration (i.e., design value) for the Vernon area, as represented by the central LA monitor, is 158 $\mu g/m^3$. If 75% of the modeled NOx is assumed to be in the form of NO_2, a common assumption for screening level modeling, then the total NO_2 impact (background plus stack impact) is 180 $\mu g/m^3$ for the DGS-ESP case. For the WGS case, however, the total concentration is 195 $\mu g/m^3$. Therefore, this simple screening analysis demonstrates that the cooler exhaust that would result from adding WGS technology has the potential to create an exceedance of the federal one-hour average NO_2 standard. Therefore, the DPEA should have evaluated this potentially significant air quality impact. We note that the DPEA does not even recognize this new standard as an applicable requirement. At a minimum, the District should evaluate the extent

to which the Rule 2002 amendments will cause or contribute to an exceedance of the new federal one hour nitrogen dioxide standard.

2-13 Cont'd

As discussed above, the DPEA concedes that the Project will have a significant GHG impact. As noted above, that triggers the need to propose all feasible mitigation measures. The DPEA, however, only proposes GHG-1 and GHG-2 (i.e., use of recycle water, see p. 4-31), which are inadequate from a CEQA perspective. At a minimum, the District should follow the outline of proposed GHG mitigation measures in the recently released California Air Pollution Control Officers Association's *Quantifying Greenhouse Gas Mitigation Measures* (see http://www.capcoa.org/). Absent this GHG mitigation analysis, a decision maker cannot reasonably conclude that all feasible GHG mitigation measures have been applied.

2-14

Air Toxics

The DPEA should not limit the evaluation of sodium hydroxide (NaOH) operational impacts to the calculation of emissions from storage tank filling and working losses (as identified in Tables 4-8 and 4-9). The potential for NaOH emissions from the proposed wet gas scrubber should also be considered. Any time a chemical solution is sprayed into a chamber through which a gaseous stream passes; there is the potential for the resulting small droplets to be carried along with the stream as drift or mist. Therefore, worse-case emission calculations should consider NaOH slip out the WGS stack into the ambient air. We realize that mist eliminators could be installed in the WGS units to reduce these emissions, but the uncontrolled emission rate(s) should be calculated and compared to the most stringent Rule 1401 Screening Emission Level for NaOH (i.e., 0.004 pounds per hour). The cost of these controls, if necessary, should be factored into the cost effectiveness analysis. Further, the impact of the pressure drop introduced by this supplemental control system on the integrity of the overall process, including the glass furnaces, dry scrubber, and ESP controls must be considered.

2-15

Land Use

The District's technical analysis does not consider what will happen should the Owens Vernon facility be unable to afford new, yet-to-be demonstrated control configurations, or secure adjusted RECLAIM Trading Credits in sufficient quantities to continue to operate. Should the Owens Vernon facility be forced to discontinue operations, over 100,000 tons/year of recycled glass will either have to be landfilled, or shipped out of the basin. Over two to three million glass containers per day will have to be shipped into the basin to our customers. Therefore, the DPEA should be revised to consider the following impacts:

2-16

- Loss of tax revenue from closure of the Vernon facility

- Loss of employment to 260 workers
- Loss of recycle capacity, and impact on neighboring landfills or from shipment of recycle glass to other locations
- Loss of container glass capacity, and the air emissions/impacts associated with shipment of container glass into Los Angeles via ship, truck and rail

These are reasonably anticipated to occur, given that the Vernon facility is now the last remaining container glass plant in Southern California.

2-16 Cont'd

Noise

The DPEA acknowledges that SOx control equipment proposed by BARCT may add new sources of noise at affected facilities, but the DPEA concludes without substantive analysis that this additional noise is not expected to be noticeable at the property line and will be within allowable noise levels set by OSHA and local noise ordinances. Notably, the DPEA provides no quantification to support this conclusion. Significantly, this conclusion is not consistent with the Ball Foster wet scrubber retrofit project, which resulted in a significant increase in noise complaints from residents and other businesses around their El Monte facility. To address these public complaints, Ball Foster installed, at considerable expense, noise attenuators and other technology to lessen the noise impact of the wet scrubber controls. As discussed elsewhere in our comments, technical problems associated with the wet scrubber technology could not be overcome, such that the wet scrubber was removed, and replaced with dry scrubber/ESP controls. The DPEA should be revised to properly summarize the direct experience at Ball Foster, quantify the incremental acoustic impact of wet scrubber technology on all affected units, and provide mitigation, as necessary, to comply with OSHA and local noise ordinances.

2-17

Water Demand

The DPEA concedes that the Project demands 52,272 gallons per day ("gpd") for construction activities and up to 883,368gpd for operation. DPEA, pp. 4-67, 4-83. To meet this significant demand, the DPEA states that SCAQMD staff has been coordinating with various water suppliers who claim that there will be sufficient water supplies for the Project. The DPEA, however, does not provide substantial evidence to support that assertion or factually demonstrate that adequate water supplies are available. The DPEA also acknowledges that there are no guarantees for substantial portions of the water supplies that it factored into the supply and demand analysis. In other words, the DPEA is not only relying on speculative water sources, but also relying on unsupported water supply claims. That is impermissible.

2-18

In addition, the DPEA's proposed water supply mitigation measures (i.e., HWQ-1 and HQW-2) are inadequate because the measures do not minimize the water demand impacts of the Project. Also, the DPEA concludes that water demand impacts are significant, but then fails to propose all feasible mitigation measures. Worsening matters, the DPEA's cumulative impact analysis provides no meaningful assessment of the Project's cumulative water demand impacts. These are clear failures of CEQA requirements. 2-19

Water Quality

The DPEA's conclusion regarding project operational water quality impacts is as follows: "Since all of the affected facilities have been shown under both options of the proposed project to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated as a result of the proposed project. Thus, the operational impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant." (p. 4-79). What the DPEA did not address is that the installation and use of WGS at the existing glass plant would add a new and different stream to the wastewater. Therefore, the wastewater permit would need to be modified, and the conclusion that the operational impacts are expected to be less than significant is flawed. 2-20

As indicated in our attached September 22, 2010 technical comments, container glass manufacturing operations have experienced significant difficulties in treating the selenium content of wastewater from wet gas scrubbers to meet Regional Water Quality Control Board (RWQCB) industrial wastewater discharge standards. Selenium is used to refine flint (clear) glass container bottles to improve the clarity of the final product. Following the installation of wet gas scrubber technology at the Ball Foster El Monte facility, the facility was unable to comply with its selenium discharge limit. The Ball Foster facility was cited by the RWQCB, and paid substantial fines to settle these violations. Despite a concerted effort and the application of several chemical treatment technologies, the facility was unable to identify a wastewater treatment technology to address these exceedances. As indicated in our technical comments, the Ball Foster facility scrapped the wet scrubber technology, and with the approval of District engineering staff, installed dry scrubber/ESP controls to meet BACT. This effectively eliminated the high-selenium wastewater. The DPEA should therefore properly inform District decision makers of these significant technical challenges associated with treating container glass wet gas scrubber wastewater. In addition, the engineering assessment should not conclude that an expenditure of $225,000 will be sufficient to address high selenium loading in wet gas scrubber wastewater, absent a technical analysis to support this assumption. 2-21

Re: Proposed Amended Regulation XX – Technical Comments - Owens-Brockway Glass Container Inc. Vernon Facility (SCAQMD ID 7427)

Dear Ms. Pham:

By this letter, Owens-Brockway Glass Container Inc. Vernon, California facility (Owens Vernon facility) provides its comments on the August 17, 2010 draft proposed amendments to Regulation XX as presented and discussed during the September 8, 2010 Public Consultation Meeting. Specifically, we provide to the District additional technical information that should be considered in setting Best Available Retrofit Control Technology (BARCT) for glass manufacturing. As summarized below, the Owens Vernon facility has already installed BARCT, which the District has recognized as Best Available Control Technology for the control of sulfur oxides. Our outside technical consultant has found no example of a glass container manufacturing facility with a control configuration as suggested by the December 2008 ETS, Inc. engineering evaluation and the December 2009 District draft staff report. In addition, we have identified numerous technical feasibility issues not considered in the District's analyses to date. Therefore, for the reasons outlined below, the Owens Vernon facility should be excluded from the facilities subject to the SOx shave proposed by the Rule 2002 revisions. 2-22

To put these technical issues in perspective, it is helpful to have an understanding of our plant's customers, employees, and our facility's role in sustainable manufacturing resources in the Los Angeles area. The Owens Vernon facility has been in business for over 70 years. Over the past 25 years, some six individual glass container manufacturing facilities have ceased to operate in the Los Angeles basin, such that the Owens Vernon facility is the only remaining container glass manufacturing facility located within the District. We produce between 2 and 3 million glass bottles per day on five production lines pulling from two furnaces and purchase approximately 330 tons/day of recycled glass. We have 260 employees that represent 15 different countries and territories of origin, over one third of whom have worked at the Owens Vernon facility for over 20 years. The average salary for Owens Vernon staff is three times the minimum wage, 2-23

with medical, dental and pension plan benefits. Our customers are here in Los Angeles; over 75% of our shipments are to customers within 25 miles of the of the Owens Vernon plant. Thus, the Owens Vernon Facility plays a vital role in maintaining sustainable container glass manufacturing in the Los Angeles area.

2-23 Cont'd

It is also important to put our environmental controls into proper perspective. Owens has been an innovator of emission controls on glass manufacturing. At significant cost, our company implemented oxygen-fuel fired glass manufacturing technology to reduce nitrogen oxide emissions from high temperature furnace exhaust. This innovative process control technology was installed to comply with NOx RECLAIM allocations. To comply with SOx RECLAIM, Owens Vernon first employed a SOx control system that injected a water-based sorbent into the exhaust stream prior to the existing electrostatic precipitators (ESPs). However, our facility experienced numerous problems with this technology [*Petition for an Ex Parte, Emergency, and a Short Variance*, Case No. 4472-9, Facility ID 007427, May 15, 1997, paragraphs 6-10]. We also note that the Ball-Foster El Monte facility experienced significant operating problems with its wet scrubber technology, which resulted in the company's decision to replace the wet scrubber with a dry scrubber followed by an electrostatic precipitator [*Petition for Modification and Extension of a Variance*, Case No. 108-20, Facility ID 108701, April 9, 1997, paragraphs 6-14].

2-24

Therefore, with the District's approval, Owens Vernon selected dry scrubbing technology (Trona injection) to reduce sulfur dioxide to comply with RECLAIM. It is important to note that this dry scrubbing technology was identified by the District as Best Available Control Technology (BACT) for the control of sulfur oxides. The dry scrubber controls are followed by the existing three ESPs that operate in parallel to remove entrained Trona sorbent and particulate emissions from the two glass melting furnaces. These technologies reduce sulfur oxide emissions by up to 90%. It is critical to note that the Owens Vernon facility actual SOx emission rate (approximately 0.6 pounds/ton of glass pulled) is significantly lower than the permitted SOx emission rate established for the container glass manufacturing facility in Seattle, Washington that is controlled by the wet scrubber technology evaluated by the District in its BARCT determination.

With this background, we now turn to consider technical issues raised by the District's BARCT analysis that supports the Rule 2002 revisions. As a threshold matter, we know of no container glass facility that currently operates the control configuration that is being proposed as BARCT:

- Dry scrubber/Trona injection, followed by
- Three separate electrostatic precipitators operating in parallel, followed by
- Two wet scrubber (50% NaOH) towers.

The December 2008 engineering evaluation suggests that this is technically feasible and cost effective for the Vernon facility. Owens retained Ashworth Leininger Group (ALG) to review this engineering evaluation, and the technical feasibility of installing retrofit wet scrubber technology at the Vernon facility. Their comments are attached for your review. We note the following:

2-25

- ALG is not aware of any glass manufacturing facility that currently operates with the BARCT control configuration recommended by staff for Owens Vernon: dry scrubbers followed by ESPs followed by wet scrubbers;
- To maintain the current redundancy of controls, which is essential as the glass melting operations cannot be temporarily shut down, it will be necessary to install three wet scrubbers instead of the two suggested in the ETS, Inc. report;
- The ETS, Inc. report does not consider/address how proper operating pressures will be maintained in both the oxy-fuel furnaces and existing ESP controls when the new wet scrubbers are added onto this system;
- The ETS, Inc. report does not address how the integrity of the wet scrubbers will be maintained should there be an upset condition in the ESPs, which will result in high particulate loadings directed to the wet scrubbers;
- The ETS, Inc. report does not properly consider site limitations associated with adding three wet scrubber towers that will be required to control the three existing ESP control systems;
- The ETS, Inc. report does not include all foreseeable costs associated with the wet scrubber retrofits;
- The ETS, Inc report provides no technical analysis of how wastewater discharges will meet RWQCB effluent limitations for selenium and other inorganic compounds;
- If retrofit with wet scrubber technology, the new exhaust gas will have a significantly lower temperature, and therefore significantly reduced plume buoyancy. No modeling analysis has been presented to demonstrate that ambient impacts from the Owens Vernon facility glass manufacturing operations will continue to comply with state and federal ambient air quality standards, including the new short term federal nitrogen dioxide standard; and

- The ETS, Inc. report and District draft staff report/evaluations do not properly consider the acute health risks posed by sodium hydroxide emissions from the wet scrubbers, as required by District Rule 1401.

2-25 Cont'd

Finally, the District's technical analysis does not consider what will happen should the Owens Vernon facility be unable to afford new, yet-to-be demonstrated control configurations, or secure adjusted RECLAIM Trading Credits in sufficient quantities to continue to operate. Should the Owens Vernon facility discontinue operations, over 100,000 tons/year of recycled glass will either have to be landfilled, or shipped out of the basin. Over two to three million glass containers per day will have to be shipped into the basin to our customers. We believe that this issue, along with the land use impacts associated with urban decay resulting from our plant's potential closure and adverse impact on environmental justice areas should be addressed in the District's Program Environmental Assessment for the proposed rule change. Our formal comments on that document will be provided by October 1, 2010.

2-26

We recognize that these comments are provided at the end of this public comment period for Rule 2002 modifications. If you think helpful, we would be willing to meet with you to clarify our comments. We look forward to working with the District to finalize Rule 2002 amendments.

Very truly yours,

Dean Harris

Ashworth Leininger Group Comments on Proposed Amended Rule 2002
On Behalf of Owens-Brockway Glass Container Inc.

Ashworth Leininger Group (ALG) was retained by Owens-Brockway Glass Container Inc. (Owens) Vernon facility to review the August 17, 2010 draft Rule 2002 rule modifications, and data provided by the South Coast Air Quality Management District (District) staff at the September 8, 2010 Public Consultation meeting[1]. Comments 1-3 address proposed amended Rule 2002 revisions; comments 4-8 address technical issues associated with the Best Available Retrofit Control Technology (BARCT) analysis.

Specific Comments on Proposed Amended Rule 2002:

1. Owens-Brockway should be included in the list of SOx RECLAIM holders exempted from proposed "shave". As discussed further below, Owens Vernon has already installed dry scrubbing technology considered by the District to be Best Available Control Technology (BACT). Further, there are unique site conditions that have not been fully evaluated in the December 2008 ETS, Inc. engineering report, and make installation of additional retrofit controls infeasible. Since additional SOx controls are infeasible (as discussed below), it is inappropriate to subject Owens to the same SOx shave requirements as the other ten SOx RECLAIM participants impacted by section (f)(1)(J). For these reasons, the Owens Vernon facility should be added to Table 5 that lists the RECLAIM facilities that are exempted from the proposed SOx RTC adjustments ("shave") described in section (f)(1)(J). 2-27

2. Table 4 should be revised to remove the Best Available Retrofit Control Technology level for container glass melting furnaces. As discussed in more detail below, Owens has already installed dry scrubbing technology equivalent to what should be considered as Best Available Retrofit Control Technology (BARCT) to reduce container glass furnace SOx emissions. As discussed below, the District's evaluation of wet gas scrubber (WGS) controls with respect to the existing Owens facility process and control configuration did not properly consider the technical and operational issues associated with installing retrofit WGS controls in conjunction with existing dry scrubbers and electrostatic precipitators. The evaluation did not consider the need to install three, not two, WGS units, nor physical site limitations with respect to installing three new WGS units (in addition to the existing two dry scrubbers and three ESPs.) The District's evaluation also 2-28

[1] The rule development history for the proposed amended Rule 2002 is somewhat complex and lengthy. Briefly, Table 4 of Proposed Amended Rule 2002 indicates that BARCT for container glass melting furnaces is a SOx emission rate of 5 ppm, equivalent to 0.03 pound of SOx per ton of glass pulled. The District's December 2009 *Draft Staff Report for Proposed Amended Regulation XX* identifies this as representing 95% control from Owens' 2005 SOx emission rate of 0.62 pound per ton of glass pulled. As the final BARCT study report indicates, emissions at the Owens facility are already controlled with two dry scrubbers, followed by three electrostatic precipitators (ESPs). Based on information presented by the District at its September 8, 2010 SOx RECLAIM Public Consultation Meeting, Tier I BARCT had previously been determined to be the 1993 average Reported Value of 2.51 pounds SOx per ton of glass pulled; therefore the proposed BARCT level represents a 99% reduction in SOx emissions.

did not consider the severe operational difficulties encountered by another container glass manufacturer when it attempted to operate a WGS in conjunction with an oxy-fueled glass furnace. As described below, the engineering analysis did not fully calculate the cost of WGS retrofits and RECLAIM compliance modifications. Considering these issues, BARCT for container glass melting furnaces should not be established any lower than presently achieved at Owens with its dry scrubbers operated in conjunction with ESPs.

2-28 Cont'd

3. Section (f)(1)(Q) should be clarified to indicate that it applies only to new SOx RECLAIM program entrants. Rule 2002 section (f)(1)(Q) provides that:

> "SOx Allocations for compliance years 2012 and after, for facilities that enter RECLAIM after (date of adoption) and for basic equipment listed in Table 4 shall be determined according to the BARCT level listed in Table 4 or the permitted emission limits, which ever is lower."

2-29

Section (f)(1)(Q) should be clarified to indicate that SOx allocations for facilities entering RECLAIM after rule adoption (new facilities) with equipment listed in Table 4 will receive allocations for 2012 and later based on the BARCT limits in Table 4 or based on permitted levels (whichever is lower). As written, section (f)(1)(Q) could be interpreted as also requiring allocations for existing facilities with basic equipment listed in Table 4 be reduced to Table 4 BARCT levels effective 2012, which runs contrary to the provisions of proposed sections (f)(1)(I) and (f)(1)(J).

Specific Comments on Best Available Control Technology:

The Owens Vernon facility operates two oxy-fuel furnaces (Furnace B, rated at 60 MMBtu/hr, and Furnace C, rated at 100 MMBtu/hr). These two process units are controlled by dry scrubber sorbent (Trona) injection, followed by three 3-field electrostatic precipitators (ESPs) which remove the sorbent and particulate emissions associated with glass melting. The use of three ESPs is required to provide redundancy in controls, as the underlying equipment (glass melting furnaces) cannot be shut down. Furnace B has a permitted SOx emission rate of 3.15 pounds SOx/ton of glass pulled; Furnace C has a permitted SOx emission rate of 2.4 pounds SOx/ton of glass pulled.

2-30

Following the adoption of RECLAIM, the facility first installed a United McGill semi-dry SOx scrubber on Furnace B in 1994. This control configuration proved infeasible in the long term due to maintenance and operational issues, as agreed to by the District Hearing Board, and was subsequently replaced by a dry scrubber, which was optimized through the use of Trona sorbent materials. Testing on the unit demonstrated up to 90% control efficiency relative to SOx; however, the systems typically operate at a 75-85% control level. With this general background, we provide specific comments related to the District's BARCT evaluation and proposed control level:

4. The emission reductions associated with the specific combination of controls relied upon by the District to achieve its proposed BARCT level has not been achieved in practice. We know of no installation in which a facility relies upon dry scrubbing, dry ESPs, followed by wet scrubbing to achieve the emission reductions anticipated by the District. Further, we have talked to equipment vendors, engineering/environmental staff at glass manufacturing facilities, and independent consultants, and they are aware of no such control configurations. We anticipate such a combination of controls would encounter the following challenges:
    - There is no discussion as to why two wet scrubbers (with a combined capacity of 60,000 cfm) are to be applied to control emissions from three ESPs (with a combined capacity of 90,000 cfm). To maintain the quick dispatch, operating pressures (addressed further below) and current redundancy in the existing control configuration, a single wet scrubber is required to follow each ESP. Thus, three wet scrubbers will be required to support the Vernon facility, as opposed to the two units considered in the ETS, Inc. analysis.
    - Pressure drop over the dry scrubber and dry ESP stages could preclude the wet scrubber stage from achieving the anticipated SOx removal efficiencies, and unless properly managed, can adversely affect the operation of the oxy-fuel furnace itself. Management of the furnace operating pressures and pressure drop across all three controls (Trona injection, ESP, wet scrubber) would require use of variable fans/process controls that are not addressed in the December 2008 ETS, Inc. report. Failure to properly maintain pressures throughout the system will compromise the furnace operation (including potential catastrophic failure), particulate control and sulfur oxide control efficiencies. In addition to these technical issues, the costs for viable induction fan motors/drives and process controls do not appear to have been considered.
    - Injection of sodium sesquicarbonate (Trona) in the dry scrubber stage results in increased particulate loading that is removed by three ESPs operating in parallel. While there is redundancy in the use of three ESPs, the ESP control units break down and when this occurs, increased particle loading to be routed directly to the wet scrubbers would occur at an uncontrolled rate of 120-150 pounds/hour. No discussion is provided as to how the wet scrubber technology will be protected when there is an upset condition in the Trona injection/ESP operation. This is a significant issue as high particulate loading will foul and compromise the wet scrubber technology.
    - We note that the particulate loading design value provided by ETS to the various equipment vendors understated the particulate loading allowed by the permit by an order of magnitude (0.008 grains/dry standard cubic foot cited in the ETS report versus the permit limit of 0.08 grains/dry standard cubic foot). The ETS, Inc. analysis should be corrected, and vendors contacted to assure that increased particulate loading can be accommodated by the wet scrubber technology.
    - Selenium is present in Owens' exhaust gas. Large quantities of water will be required to cool the exhaust gas to the temperature range required for the wet scrubbers, as well as for operation of the wet scrubbers. This water will require

2-30 Cont'd

treatment to remove the selenium prior to off-site disposal. There is no detailed analysis of the technical feasibility to treat this stream; rather the ETS, Inc. report assumes that one of four options is feasible at a cost of $225,000, which in our view ignores technical issues and simply throws money at the problem without solving this issue. As an example, one of the options proposed in the ETS report for treating wastewater (Option 3 on page 6 of the ETS report) is to send blowdown from the scrubbers to a storage tank and then spray it into the duct ahead of the precipitators to evaporate the water and collect the dry particulate in the ESPs. This does not account for the PM loading to the ESPs associated with Trona injection, does not address whether the exhaust temperature will be sufficient to support evaporation of the water, nor does it account for the potential issues associated with adsorption/absorption of the water by the Trona and particulate matter.

Owens encountered a nearly identical situation in 1997, when it experienced moisture buildup in the ESPs resulting in short-circuits within the units, as a result of water injection prior to the ESPs and insufficient temperatures to evaporate the water. At the time, Owens was operating a semi-dry scrubber on Furnace B, in which soda ash and water were injected into the furnace exhaust prior to the ESP. Previously, Owens had been operating three furnaces, and the combined exhaust temperature was sufficient to support evaporation of the injected water. However, once Furnace A was shut down, exhaust temperature dropped, resulting in condensation buildup in the ESPs. The condensation buildup, combined with the ESP dust, became acidic and corroded wiring within the ESPs. Acidic water also began leaking outside the ESPs, necessitating additional abatement efforts. Owens attempted to prevent heat loss by adding insulation on the ducting, which proved insufficient. Owens also considered raising the scrubber exhaust temperature, but recognized that this was infeasible since it would require reducing the exhaust gas residence time and reduce the scrubber control efficiency [*Petition for an Ex Parte, Emergency, and a Short Variance*, Case No. 4472-9, Facility ID 007427, May 15, 1997, paragraphs 6-10].

2-30 Cont'd

- We note that the Ball Foster El Monte facility was unable to achieve compliance with its selenium discharge permit limits when operating a wet scrubber. Based on discussions with former company staff, high selenium concentrations in wastewater discharge resulted in non-compliance penalties and was a key consideration in the decision by the company to switch to dry scrubber control technology.
- No analysis is provided of the acute health risk posed by emissions of 50% NaOH scrubber mist that will be released from the operation of the three wet scrubbers, and whether this incremental acute health risk is within District Rule 1401 requirements. The District's CEQA analysis improperly focuses on storage of sodium hydroxide, and fully ignores emissions from the wet scrubber stack. As indicated below, this toxics analysis is especially important, as the wet scrubber controls require that exhaust temperatures be reduced to ~150

degrees F. This lower exhaust temperature will reduce the buoyancy of the plume, and increase ambient concentrations near the facility.

- No analysis has been performed to show compliance with the new federal ambient standard for nitrogen dioxide. The wet scrubber technology requires that the temperature of the exhaust gas has to be reduced from 650 degrees F to ~150 degrees F. This significant reduction in exhaust temperature will significantly reduce the buoyancy of the plume, and thus increase ambient concentrations of exhaust gases, including nitrogen dioxide, particulate, air toxics, and combustion gases. This refined analysis must be performed as it will be required by the District.
- As we will comment as part of the CEQA documentation, the District has not evaluated the ability to introduce a new hazardous material (50% sodium hydroxide solution) into a manufacturing process consistent with the California Legislature's directive under the new Green Chemistry Initiative, which will be in effect when SOx emission reduction process modifications will be made.

5. Adding a wet scrubber stage to the Owens SOx emissions control system is technically infeasible. Beyond the technical issues identified in the immediately preceding comment, Owens will encounter the following issues which preclude addition of a wet scrubber stage:
   - There is insufficient space next to the existing controls to install three wet scrubbers, stacks, and necessary support equipment adjacent to the existing facility. As explained to ETS at the time of their site visit, there is a single 14'x22' pad proximate to the existing three ESPs. In our experience, this is insufficient to locate three wet scrubber towers rated at 30,000 cfm each, and associated pumps/Continuous Emissions Monitoring Systems (CEMS) and related process equipment.
   - Owens would have only two options for installing the required wet scrubber controls: 1) installing the control systems in its parking lot located to the east of the existing ESPs and running ducting over the top of a building (which would pose unacceptable safety issues); or 2) tearing down a building. No cost/feasibility analysis was provided for these two options.

2-30
Cont'd

6. Costs associated with BARCT for container glass melting furnaces is understated. Costs are underestimated for the following reasons:
   - As previously stated, BARCT for container glass melting furnaces is currently established at a level of 2.51 pounds of SOx per ton of glass pulled. Based on the District's evaluation of BARCT, achieving the proposed BARCT level of 0.03 pound SOx per ton of glass pulled would require a combination of dry scrubbers, dry ESPs, and wet scrubbers. Therefore, at a minimum, the costs for all three technologies need to be incorporated into the cost-effectiveness analysis.
   - The BARCT cost estimates need to account for three wet scrubbers and associated ducting/support equipment as each ESP will require a dedicated wet scrubber to maintain needed control redundancy for the oxy-fuel furnaces.

- As indicated above, the ETS report provides no basis for the estimated $225,000 in capital costs associated with wastewater treatment, which can be significant as selenium is especially hard to treat to RWQCB discharge limits.
- No costs are provided for the construction of three new exhaust stacks, for relocation and installation of the CEMS on each of these three stacks, for permitting of the CEMS with the District's RECLAIM group, for the new Relative Accuracy Test Audits that must be performed, or for the costs of RTCs to cover the missing data that will be recorded by the new CEMS. Our prior experience on CEMS monitoring systems indicates that costs for three such systems can exceed $250,000 for each CEMS.
- No technical data are provided to support the estimated 25-year useful life of a caustic wet scrubber. Our experience with caustic wet scrubbers suggests a shorter useful life (10-15 years), which is also typical of useful life assumptions based on EPA and other local air district control technology analyses.

2-30
Cont'd

7. <u>The District did not consider the implementation challenges faced by Ball-Foster when attempting to utilize a wet scrubber to control SOx emissions from an oxy-fueled glass furnace in the mid-1990s</u>. In February 1995, Ball-Foster converted its regenerative glass furnace to oxy-fuels operation at its El Monte facility. Previously, the furnace had utilized a venturi wet scrubber to control PM emissions. After the conversion, Ball-Foster reconnected the furnace to the wet scrubber. Starting one month later, the scrubber began experiencing numerous equipment failures, including component overheating and damage, plugging, and excessive solids buildup – prompting numerous emergency breakdowns. After struggling with the scrubber operational problems for a year, Ball-Foster informed the District Hearing Board that it intended to replace the wet scrubber with an ESP to control particulate emissions, and a dry scrubber to control SOx emissions. By mid-1997, the wet scrubber had been removed and replaced by a dry scrubber and ESP [*Petition for Modification and Extension of a Variance*, Case No. 108-20, Facility ID 108701, April 9, 1997, paragraphs 6-14]. Like the Ball-Foster furnace, both of Owens' glass furnaces are oxy-fuel fired.

8. <u>BARCT for container glass meting furnace SOx emissions should be established as the emission rate achievable by Owens' current dry scrubber/ESP control system</u>. Based on information presented in the District's December 2009 Draft Staff Report, this would be a level of between 0.62 and 1.05 pounds SOx per ton of glass pulled, and represent the combination of process modifications and control technology. Notably, this SOx emissions limit is below the permitted SOx emission rate (1.6 pounds SOx/ton of glass pulled) established for the Seattle, Washington container glass plant that that is controlled by the wet scrubber technology evaluated by the District in its BARCT determination.

Responses to Comment Letter #2
(Owens-Brockway Glass Container, October 1, 2010)

2-1 Individual responses to the technical issues and background comments submitted have been prepared and begin with Response to Comment 2-3. Regarding the claim that the facility is already at BARCT, see Response to Comment 2-4.

2-2 Owens-Brockway Glass Container Inc. (Vernon Branch) is a subsidiary of Owens-Illinois, Inc. According to the website for Owens-Illinois, the parent company of Owens-Brockway, in 2009 Owens-Illinois had 22,000 employees in 21 countries with net sales of $7.1 billion[1] and a gross profit margin of 21 percent. SCAQMD records confirm that Owens-Brockway is the only glass container facility in the district.

According to the proposed amendments, there is an adequate amount of RTCs in the current SOx RECLAIM market that affected facilities could use. Currently, the surplus of RTCs in 2005 is about 1.73 tons per day and the surplus of RTCs in 2008 is about 2.55 tons per day (out of total RTC holdings of 11.77 tons per day). The amount of RTCs converted from ERCs contributed to the size of the surplus. In addition, the amendments instituted several safety valves to prevent potential facility shutdowns: 1) gradual annual reductions with extended compliance schedule (2012-2019); 2) monitoring of RTC price trend (12 month rolling average), 3) hold Public Hearing if RTC price exceeds $50,000 per ton (discrete price), 4) ability for Governing Board to set aside (give back) up to 100 percent of RTC reductions for any year when RTC price exceeds $50,000 per ton.

Based on the Staff Report the cost-effectiveness for the glass plant is estimated to be $9,000 per ton of SOx reduced. The average annual cost of complying with the proposed requirements is estimated to be $0.52 million (socioeconomic report). Based on the above assumptions, Owens-Brockway Glass Container facility is not expected to shutdown due to the requirements of the proposed amendments.

2-3 The particulate buildup problems that Owens-Brockway and Ball-Foster Glass Container encountered between 1994 and 1997 are not expected to occur with the WGSs proposed by the consultant ETS Inc. (ETS) because ETS proposed to remove the two existing dry gas scrubbers located upstream of the ESPs and replace them with two WGSs located downstream of the ESPs. The ESPs located upstream of the wet gas scrubbers will collect particulate matter and prevent excessive particulate buildup in the wet gas scrubbers. In addition, fine powder Trona injection needed for the dry gas scrubbers would no longer be needed, and thus any Trona leakage to the ESPs would drop to zero, and the particulate loading to the ESPs would be reduced significantly. Detailed explanations on the problems occurred at Owens-Brockway and Ball-Foster Glass Container encountered between in 1994 and 1997 are presented in the following paragraphs.

Owens-Brockway

Owens-Brockway currently operates two oxy-fuel furnaces (Furnace B, 60 MMBtu/hr, and Furnace C, 100 MMBtu/hr). Previously, Owens-Brockway operated three furnaces

[1] O-I Announces Third Quarter Earnings Conference Calland Webcast, September 20, 2010. http://www.o-i.com/nth_us.aspx?id=400; http://www.o-i.com/about_oi.aspx?id=1348 and http://www.o-i.com/nth_us.aspx?id=400

(Furnace A, B and C). In 1974, Owens-Brockway installed a United McGill semi-wet scrubber using soda ash as the scrubbing agent to control SOx. The particulate matter emissions from the three furnaces are controlled by three ESPs located downstream of the semi-wet scrubber (any two ESPs are in operation at one time, while one ESP is stand-by.) As explained by Ashworth Leininger Group (ALG), Owens-Brockway experienced numerous problems with the semi-wet scrubber and ESPs because during a period when one of the furnaces (Furnace A, non-oxy fuel furnace) was shutdown in December 1996, the exhaust temperature dropped, resulting in condensation buildup in the ESPs. ALG further explained that the condensation buildup caused corrosion within the ESPs. For this reason, Owens-Brockway had to seek several variances from the SCAQMD Hearing Board in 1997 and finally decided to remove the semi-wet scrubber and replaced the semi-wet scrubber with the two dry gas scrubbers. Trona, a very fine powder, is currently used as sorbent in the dry gas scrubbers.

SCAQMD staff believes that the problems with the semi-wet scrubber and ESPs were not caused by equipment capability, but equipment operation. Condensation problems would not have occurred in the ESPs if Furnace A were not shut down and the temperature of the flue gas entering the ESPs was high enough to prevent moisture condensation in the ESPs. The following, excerpted from Owens-Brockway Glass Container Corp.'s May 14, 1997 Petition for an Ex Parte, Emergency, and a Short Variance (Case No. 4472-9) supports SCAQMD staff's position:

> *"Prior to discontinuing the operation of Furnace A, the temperature of the combined exhausts from Furnaces A and C, when mixed with Furnace B exhaust, was high enough to keep the exhaust moisture content as vapor in the ESP. Since Petitioner has only been operating Furnaces B and C, the volume of exhaust has been reduced and the combined exhaust temperature has not been high enough to keep exhaust mixture in the form of vapor as exhaust enters the ESPs. Consequently, moisture condenses in the ESPs."*

Ball-Foster Glass Container

The problem that occurred at Ball-Foster Glass Container (aka Saint-Gobain Containers) was very different in nature than the problem that occurred at Owens-Brockway. Ball-Foster Glass Container did not use ESPs to control particulate matter. They operated a wet venturi, variable throat scrubber using soda ash as absorbent to control both SOx and particulate matter. In 1993, they converted their existing glass furnace to an oxy-fuel furnace which was operated with significantly less combustion air, which subsequently resulted in reducing the volume of exhaust flue gas from the furnace to the venturi scrubber and increasing the particulate loading to the scrubber. SCAQMD staff believes that the excessive solids build-up in the scrubber system was due to failure to redesign the venturi wet scrubber to handle the excessive particulate loading after the conversion to the oxy-fuel furnace. In 1999, Ball-Foster Glass Container removed the venturi wet scrubber and replaced it with a dry gas scrubber to control SOx and an ESP to control particulate matter.

2-4 Control technology has improved over time. The dry gas scrubbers operating at 80 percent to 90 percent control efficiency were considered as BARCT for SOx in 1994. However, between 2008 and 2010, two consultants (ETS and NEC) expressed agreement that non-regenerative wet gas scrubbers can achieve a range from 1 ppmv to 5 ppmv SOx outlet concentration (95 percent control efficiency or more from the 2005 emissions baseline, 99 percent from the uncontrolled level assuming that the dry gas scrubbers operated at 80

percent control efficiency) and thus, should be considered as BARCT for SOx for glass melting furnaces. While these two consultants recommended different types of WGSs, however, they both concurred that WGSs would be cost-effective and SCAQMD staff concurs with the consultants' recommendations. The two consultants both recommended keeping the existing ESPs in place for particulate control and placing the wet gas scrubbers downstream of the ESPs.

In addition, the proposed BARCT level for glass melting furnaces has been achieved in practice. Specifically, the Puget Sound Clean Air Agency in Seattle, Washington provided SCAQMD staff with source test and CEMS data from Saint-Gobain, a glass container facility, that demonstrates compliance with 5 ppmv SOx levels (96 percent control) via Tri-Mer's Cloud Chamber scrubber. The furnace at Puget Sound has a permit limit of 1.6 pounds of SOx per ton of glass pulled but tested at 0.0062 pound of SOx per ton of glass pulled [2, 3]. SCAQMD staff had multiple conversations with Tri-Mer about their WGS technology, and Tri-Mer indicated to SCAQMD staff that they provided many types of WGS that can be used to achieve 5 ppmv SOx outlet concentration, either packed bed, open throat, venturi, or Cloud Chamber scrubber. The Cloud Chamber scrubber can also be used as a particulate control device.

The commenter has indicated that dry gas scrubbers can achieve up to 90 percent control. It is interesting to note that Owens-Brockway currently holds 0.31 ton per day of RTCs. With the proposed RTC shave of 55 percent, Owens-Brockway remaining allocations would be 0.14 ton per day. The 2005 emissions from Owens-Brockway were about 0.2 ton per day at 80 percent control[4]. Thus, if the control efficiency of dry gas scrubbers were improved to 90 percent as the commenter notes is achievable, then Owens-Brockway would already be in compliance with the shave at 0.1 ton per day of SOx emissions[5]. However, if Owens-Brockway operators choose to install wet gas scrubbers, surplus RTCs will be created that could be sold when needed.

2-5 Regarding the comment that the Draft PEA does not demonstrate that adequate water supplies are available, see Responses to Comments 3-14, 3-19, 3-29, 3-31, 3-43, 3-45, and 3-46.

2-6 The Draft PEA concludes that the water demand impacts are significant for potable water demand, not total water. Thus, mitigation measures HWQ-1 and HWQ-2 are designed to minimize the use of potable water by utilizing recycled water instead. The SCAQMD has identified no other feasible mitigation measures (or alternatives) that would mitigate to less than significance the need for potable water. While arguing that the SCAQMD has not required all feasible mitigation, the comment fails to identify any additional measures. With regard to the content of the cumulative water demand impacts discussion, CEQA Guidelines §15130(b) requires the discussion of cumulative impacts to reflect the severity of the impacts and the likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. SCAQMD staff

[4] SCAQMD Engineering Evaluation, A/N 288744, March 1994.

[5] 80% control of 1 ton per day = 0.2 ton per day, and 90% control of 1 ton per day = 0.1 ton per day

believes the cumulative water demand impacts discussion in the Draft PEA adequately describes why they are considered to be cumulatively considerable. For additional information, refer to Chapter 5 of the PEA.

2-7 The commenter does not provide any information or other data demonstrating why the analysis of the GHG impacts and the corresponding mitigation measures are inadequate. The Draft PEA contains a detailed discussion of the GHG impacts which is supported by the extensive calculations in Appendix B. Because the GHG emissions estimates exceed the SCAQMD's CEQA significance threshold of 10,000 MTCO2eq/yr, the impacts were concluded to be significant and all feasible mitigation measures were identified. See also Responses to Comments 3-9, 3-39, and 3-40.

2-8 The range of alternatives evaluated in a CEQA document must be sufficient to permit a reasoned choice, but need not include every conceivable project alternative. CEQA Guidelines §15126.6(c) specifically notes that the range of alternatives required in a CEQA document is governed by a 'rule of reason' and only necessitates that the CEQA document set forth those alternatives necessary to permit a reasoned choice. The key issue is whether the selection and discussion of alternatives fosters informed decision making and meaningful public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative. SCAQMD Rule 110 (the rule which implements the SCAQMD's certified regulatory program) does not impose any greater requirements for a discussion of project alternatives in an environmental assessment than is required for an EIR under CEQA. The commenter's suggestion that the alternatives analysis is inadequate because none, other than Alternative A, the 'no project' alternative, specifically addresses glass manufacturing, represents a misunderstanding of the RECLAIM program. Under RECLAIM, a facility may purchase RTCs in lieu of installing control equipment. Thus, the proposed project and each of the alternatives potentially affect the subject facility because it as an affected RECLAIM facility and are evaluated as part of an overall regulatory program, which is why a Program EA was prepared. As part of a regulatory program, a smaller shave, for example, would reduce compliance obligations for all facilities that would be subject to the proposed project. Moreover, Alternative A is a required alternative (CEQA Guidelines §15126.6(e)). Finally, CEQA requires a range of reasonable alternatives (CEQA Guidelines §16126.6(a)), which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. The alternatives identified and evaluated for the proposed project comply with this and all other applicable CEQA requirements.

The NOP/IS prepared for the proposed project solicited suggestions for alternatives for the proposed project. Owens-Brockway did not submit any comments on the NOP/IS. Similarly, the commenter did not provide any specific recommendations for any alternatives beyond those evaluated in the PEA.

2-9 The commenter has misunderstood the assumptions about the timing with regard to facility operators implementing the proposed project. Under the RECLAIM program, facilities have the flexibility to install air pollution control equipment, change method of operations, or purchase RTCs to meet BARCT levels. As such, the Draft PEA has been crafted to explore multiple scenarios that illustrate the worst-case effects of applying the various SOx

control technologies along with demonstrating the flexibility that is provided by the RECLAIM program to facility operators when it comes to choosing the methods for reducing SOx emissions. Because of the program's built-in flexibility, as a practical matter, there is no way to predict what each facility owner/operator will do. However, not all of the affected facilities will need to take immediate action to comply with the proposed project.

The survey conducted by the consultants identified likely technologies that could be used to comply with reducing SOx emissions in connection with amending SOx RECLAIM rules. The following SOx control technologies were identified and environmental impacts of constructing and operating these equipment were analyzed in the PEA: WGSs, dry gas scrubbers, fuel gas treatment, SOx-reducing additives, et cetera. The focus of the environmental analysis is on WGS because their size and operating characteristics typically generate a greater number of or more substantial impacts than the other technologies (e.g., construction air quality impacts, water and hydrology impacts, et cetera).

If a facility operator chooses to install air pollution control equipment such as a WGS, the consultants' reports estimate that 18 months would be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and lining up contractors and workers. Further, to physically build a WGS, the consultants' reports indicated that an additional 18 months would be needed. The Draft PEA considers the overlapping construction of building four WGSs within the same 18-month period. This overlap could occur anytime between the date of adoption (scheduled for November 5, 2010) and full implementation (January 1, 2019). However, as a practical matter, even if a facility starts the planning and engineering process now (at the time of this writing October 2010) to design a WGS installation (and some are in the very early pre-planning stages), construction is not expected to occur sooner than 2012. For these reasons, the Draft PEA considers <u>any</u> 18-month window between January 1, 2012 and January 1, 2019 (a span of seven years) when facilities could undergo construction activities. These dates correspond to the final compliance date for the proposed project (January 1, 2019) and the first year when the RTC shave will occur (2012). Thus, the analysis in the Draft PEA has demonstrated that the peak daily construction could not reasonably occur in year 2011.

2-10 In response to the comment about the availability of wet gas scrubbers, the consultants' worked with multiple manufacturers of wet gas scrubber technology and none of the manufacturers indicated that there would be a problem with the supply chain. In response to the comment that the Draft PEA should analyze the possibility where facilities would install SOx controls within a two-year period and not a seven-year period, see Response to Comment 2-9. For a discussion about "reasonable worst case" assumptions consistent with the CEQA Guidelines, see Response to Comment 3-19.

2-11 Individual responses to the detailed comments submitted per environmental topic have been prepared and begin with Response to Comment 2-12.

2-12 While the comment states that there are no visible steam plumes at the glass melting plant or in the immediate area, SCAQMD records[6] show that there are at least three cooling towers, which are sources of steam plumes, at Owens-Brockway and at two neighboring facilities within one mile of Owens-Brockway (Henry Company located at 5731 Bickett in Huntington Park and the Seven-Up/Royal Crown Bottling Company located at 3220 East 26th Street in Los Angeles). Cooling towers, essential to industrial and commercial processes that require heat dissipation, utilize an open wet system that relies on the latent heat of water evaporation to exchange heat between the process and the air passing through the cooling tower. As the water evaporates, a stream of saturated exhaust air, a steam plume, leaves the tower. The plume is visible when the water vapor it contains condenses in contact with cooler ambient air. Depending on a cooling tower's location and the surrounding atmospheric conditions such as temperature and humidity, i.e., in an area of typically high humidity and low temperatures (near the coast) versus an area of typically low humidity and high temperatures (inland desert areas), this water-saturated air can create a visible plume.

In addition to the aforementioned facilities, there is another facility, as shown in the following satellite photo, located near the corner of 50th Street and Seville Avenue in Vernon, approximately one block away from the glass melting plant, that currently has three visible steam plumes (as identified by the ellipse) emanating from three cooling towers[7]. These plumes are also part of the existing aesthetics setting of the area surrounding the Owens-Brockway facility. This means that if all of the cooling towers are operating, depending on the ambient temperature and humidity, visible steam plumes may be present at or throughout the area near the Owens-Brockway facility. However, as noted in the Final PEA and as illustrated in the following satellite photo, because of the existing plumes, one additional plume from each WGS installed is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant. Further, because the plume from a new WGS is located in an industrial area and would likely be located approximately the same distance from residences, approximately ¼- mile away, compared to the existing plumes from the cooling towers, it would be no more noticeable to the closest residents than the existing plumes. Therefore, the conclusion that aesthetics impacts from implementing the proposed project would be less than significant continues to be valid.

[6] SCAQMD Cooling Tower Survey, 1988.

[7] http://maps.google.com/maps?f=q&source=s_q&hl=en&geocode=&q=2901+fruitland+ave,+vernon,+ca&sll=37.0625,-95.677068&sspn=25.010803,50.625&ie=UTF8&hq=&hnear=2901+Fruitland+Ave,+Vernon,+Los+Angeles,+California+90058&ll=33.998928,-118.221114&spn=0.000796,0.002567&t=h&z=19

A = Owens-Brockway, located at 2901 Fruitland Avenue, Vernon, CA

2-13 The air quality impact analysis provided by the commenter relied on USEPA's SCREEN3 model using standardized operating conditions with the primary adjustment for exhaust temperature due to the installation of WGSs. SCREEN3 is a very conservative tool used to calculate the "worst case" one-hour maximum ground level concentration from an emissions source. The impact predicted from SCREEN3 is the 100th percentile concentration. While the analysis uses the recommended 75 percent conversion rate from NOx to NO2, the predicted NO2 continues to represent the 100th percentile concentration and is not consistent with the form of the standard. The current NAAQS for NO2 is based on the three-year average of the 98th percentile of NO2. As a consequence, the predicted SCREEN3 modeled concentrations do not conform to the standard and are expected to overestimate the ground level impact.

The analysis used the three-year average 98th percentile NO2 concentration measured at Central Los Angeles (158 µg/m^3, 2006-2008) as the background to be added to the ground level impact. While the selection of Central Los Angeles NO2 as background was correctly assumed, it is important to note that construction and operation of the WGSs are not expected to occur before 2011. The analysis in the Draft PEA assumes the earliest that installation of WGSs could occur would be in 2012, but installations may occur anytime between 2012 and 2019. Ambient averages of NO2 have decreased since 2000 in the Basin and at Central Los Angeles. Three-year averages of the annual average and one-hour maximum NO2 concentrations from 2000-2002 through 2006-2008 have been reduced by 22 and 25 percent, respectively. Regional NOx emissions were reduced by 22 percent for the same period. Implementing the 2007 AQMP together with ongoing NOx emission reductions from mobile sources is projected to continue the trend of lower NOx emissions

reductions in future years. This trend will result in lower ambient NO2 concentrations throughout the Basin. Implementing the 2007 AQMP together with ongoing reductions in mobile source NOx is projected to continue the trend of lower NOx emissions in future years. This will result in lower ambient NO2 throughout the Basin. Using the 2007 AQMP NOx emissions inventory, an emissions-weighted projection of NO2 at Central Los Angeles is estimated to be reduced by approximately 17 percent from 2008 to 2012. Furthermore, the projection to 2019 estimates that the NO2 concentration should be lowered by 34 percent compared with the 2008 values.

When a 2012 estimated background is applied to the "worst-case" SCREEN3 modeling analysis provided, the impacts from the exhaust streams from the furnaces (153 $\mu g/m^3$ without WGSs and 168 $\mu g/m^3$ with WGSs) would not exceed the NO2 standard. If construction of the WGSs is delayed until after 2012, the impacts would be even lower and the NO2 standard would continue to be met.

2-14 The PEA did not include information from CAPCOA's GHG mitigation measure document because it was approved by the CAPCOA Board in August, the same month the PEA was released. It should, however, be noted that use of recycled water is consistent with water-related mitigation measures in the CAPCOA document because less energy is required to collect, treat, and redistribute to the point of use. Indeed, this is the one of only three water supply impact mitigation measures. Further, many of the mitigation measures are more applicable to regional or subregional planning agencies, e.g., increase diversity of urban/suburban developments, traffic calming measures, transit system improvements, incorporate bike lane street design, et cetera.

Because GHG impacts would occur at industrial facilities, AB 32 is mentioned in the Draft PEA as part of the mitigation measure discussion because it is an ongoing process under development by CARB. While there is nothing in CARB's adopted "early action measures" or CARB's GHG reduction measures that specifically apply to the proposed project at this time, as of this writing, CARB has not yet adopted its GHG reduction cap and trade program. When adopted, it is expected to apply to projects that will need to receive permits, including any projects that may occur as a result of amending the SOx RECLAIM program. The purpose of the discussion of AB 32 is to indicate that there are no additional feasible GHG reduction measures that the SCAQMD could adopt that could mitigate impacts from the proposed project and that would be able to go beyond AB 32 requirements. With regard to the adequacy of the GHG mitigation measures, GHG-1 and GHG-2, see Responses to Comments 3-39 and 3-40.

2-15 There is no evidence for the potential of NaOH slip from a WGS. The application of the Rule 1401 screening emission level would be justified if there were any indication of NaOH emissions. In fact, with the exhaust stream entering a WGS, the NaOH would effectively disassociate to sodium and hydroxide ions, not remain as NaOH. On this basis, there is no reason to believe that here would be NaOH slip into the atmosphere.

Regarding the commenter's claim that there will be an impact due to pressure drop, refer to Response to Comment 2-25. It is important to note that both sets of consultants in their final reports included contingencies to address equipment-specific, unforeseen circumstances such as pressure drop.

2-16 Evaluation of the SOx RECLAIM inventory indicates that the amount of unused RTCs in the SOx RECLAIM market in 2005 was 1.73 tons per day and by 2008 the amount of unused RTCs in the SOx RECLAIM market had risen to 2.55 tons per day, which would be available for use by the affected facilities. In addition, the proposed amendments include several safety valves to prevent potential facility shutdowns: 1) gradual annual reductions with extended compliance schedule (from 2012 to 2019); 2) monitoring of RTC price trend over a 12-month rolling average; 3) hold public hearing if RTC price exceeds $50,000 per ton (discrete price); and 4) ability for the Governing Board to set aside (give back) up to 100 percent of RTC reductions for any year when RTC price exceeds $50,000 per ton.

Further, the cost-effectiveness of the glass plant complying with the proposed project is estimated to be $9,000 per ton of SOx reduced. The average annual cost for Owens-Brockway to comply with the proposed project is estimated to be $0.52 million (socioeconomic report). Moreover, as discussed in Response to Comment 2-4, Owens-Brockway may be able to comply with the proposed RTC shave with its current control equipment. For these reasons plus the fact that in 2009 Owens-Brockway had net sales of $7.1 billion (see Response to Comment 2-2), Owens-Brockway is not expected to shutdown their operations due to the requirements of the proposed amendments. See also Response to Comment 2-26.

2-17 The commenter implies that the noise impacts from installing a WGS at the Ball-Foster facility in El Monte should be applicable to the Owens-Brockway facility located in Vernon. Further, the commenter asserts that installing a wet gas scrubber, "…resulted in a significant increase in noise complaints from residents and other businesses." The comparison with regard to residences is not applicable to the Owens-Brockway facility because the Ball-Foster facility is located adjacent to residences while the Owens-Brockway facility is located in an industrial area approximately ¼-mile away from the nearest residences, which is consistent with Vernon's Noise Element Policy, N-2.3: Prohibit the establishment of any new noise-sensitive land uses in Vernon, including but not limited to residences, schools, day-care facilities, and community facilities.

Vernon's Noise Element Policy states, "…In general, industrial noise within the City is not considered excessive because Vernon is a predominantly industrial city with few noise-sensitive properties." The Owens-Brockway facility currently operates scrubbers and has not received reports of any noise problems or complaints from neighboring industrial/commercial facilities. The conclusions in the NOP/IS for noise impacts were based on the potential replacement of two existing dry gas scrubbers with two new WGSs at the Owens-Brockway facility. Since the noise from the existing scrubbers would be replaced with equipment rated at a similar noise profile, any change in the noise level is expected to be minimal relative to the current noise baseline of the facility. A previous installation of WGS technology within the district was rated about 85 decibels (dBA)[8].

When a distance is doubled from a point source, the sound level decreases by six dBA[9]. By applying an estimated six dBA reduction for every doubling distance, for a WGS sound level of 85 dBA at 50 feet, the sound level will be 79 dBA at 100 feet, 73 dBA at 200 feet,

[8] Final Environmental Impact Report for: ConocoPhillips Los Angeles RefineryPM10 and NOx Reduction Projects: http://www.aqmd.gov/ceqa/documents/2007/nonaqmd/cp/cp_feir.html.

[9] A Guide to Noise Control in Minnesota, Minnesota Pollution Control Agency, Distance Attenuation Estimations, March, 1999. http://www.nonoise.org/library/sndbasic/sndbasic.htm

67 dBA at 400 feet, 61 dBA at 800 feet, and 55 dBA at 1,600 feet. As a point of comparison, according to the City of Vernon's Noise Element background noise levels in residential areas are generally within the range of 60 dBA to 70 dBA, however, noise levels can be as high as 85 dBA near the Burlington Northern Santa Fe Railroad tracks to the northeast of the Owens-Brockway facility (See Figure N-4, City of Vernon Noise Element[10]). It is important to note that there are no residences within ¼-mile (i.e., 1,320 feet) of the Owens-Brockway facility as the nearest residence is located at approximately 1,420 feet of the facility. Similarly, it is not reasonably foreseeable that the replacement of two dry gas scrubbers with two wet gas scrubbers with similar noise profiles at the Owens-Brockway facility would create an increase in noise that would be discernable from the existing background noise in the area.

2-18 Regarding the adequacy of water supplies for the proposed project and specific to water supplies in the City of Vernon, see Response to Comment 3-29.

2-19 Regarding the feasibility of mitigation measures, HWQ-1 and HWQ-2, and the cumulative water demand analysis in the Draft PEA, see Response to Comment 2-6.

2-20 When the consultants conducted a site visit of the glass plant, analyzed potential BARCT for the facility, and identified the potential environmental impacts that may occur as a result of installing BACT, the consultants also provided a copy of the report for Owens-Brockway personnel for review and comment. During that process, the Owens-Brockway representatives did not provide any indication that there would be a new and different wastewater stream resulting from the new WGSs. Further, when SCAQMD staff surveyed the Owens-Brockway facility regarding their water and wastewater streams, facility operators did not provide a copy of the requested wastewater permit. The commenter, in raising the issue now, has not provided any substantiating evidence to support the claim that there would be a new wastewater stream. SCAQMD staff has limited information on Owens-Brockway's current wastewater setting and permit specifications because this information was not provided by the operators. Consequently, SCAQMD staff used a surrogate analysis based on the available wastewater data on an existing WGS installation in the District. Further, based on the potential increase in wastewater that may occur at the Owens-Brockway facility, SCAQMD staff does not believe that if WGSs are installed at the glass melting plant that there will be a need to revise the wastewater permit because facilities typically operate at less than maximum capacity to ensure no violations. Further, the commenter did not provide additional information demonstrating that the anticipated increase in wastewater stream as a result of installing a WGS would require modifications to any existing wastewater limitations. Therefore, based on the available information, the comment does not provide evidence refuting SCAQMD staff's conclusion that wastewater impacts from the proposed project would require modifications to existing waster limitations or otherwise create significant adverse wastewater impacts. See also Response to Comment 2-21.

2-21 The proposed project for Owens-Brockway, as confirmed by both sets of consultants, requires the decommissioning of the two existing dry gas scrubbers and the installation of two new wet gas scrubbers (WGSs) downstream from (after) the existing ESPs. The

[10] The City of Vernon General Plan and Noise Element can be found at the following link: http://www.cityofvernon.org/assets/docs/General_plan.pdf.

selenium that is added to the glass manufacturing process is in the vapor phase as it exits the furnaces and enters and exits the ESPs as selenium oxide (SeO_2) due to the high temperature. Any gaseous phase selenium that is currently exiting the ESPs is being discharged into the atmosphere. At the very minimum, the WGSs installed after the ESPs will cool the gaseous phase selenium oxide into a solid state, which could then be scrubbed out of the flue gas to be retained in the scrubber effluent solution, and thus, preventing the selenium compound from being discharged into the ambient air. ETS provided several different options for the facility to consider for treatment of the WGS waste stream. Options 1 through 3 involve processing the liquid blowdown from the scrubbers and reintroducing the solids into the process before the ESPs. In particular, Option 3 will not introduce excessive particulate loading to the ESPs since Trona will no longer be utilized as a result of the removal of the dry gas scrubbers from the process (also refer to Response to Comment 2-30). ETS believed that the budgetary allotment was sufficient to address these waste stream considerations. The District recognizes that there are engineering design challenges (e.g., waste stream handling, pressure drop, plugging, et cetera) associated with the installation and operation of WGS technology, but these challenges are not insurmountable within the budgetary framework of the consultants' recommendations.

2-22 This comment is a summary of some of the main points made in subsequent comments in this letter. Therefore, for specific responses to each point refer to Responses to Comments 2-23 through 2-30.

2-23 See Response to Comment 2-2.

2-24 See Responses to Comments 2-3 and 2-4.

2-25 Two sets of consultants, ETS and NEC, visited the Owens-Brockway facility, collected data, interviewed facility representatives and then independently ascertained that WGSs are technically and economically feasible for this facility's furnaces. Both ETS and NEC have direct experience in DGS and WGS technologies, as well as ESPs, as applied to furnace operations at Owens-Brockway facility. SCAQMD staff sent Owens-Brockway's comment letter and SCAQMD staff responses to the consultants for their input, and their input is incorporated into this response[11].

The consultant's (ETS) analysis of the Owens-Brockway facility was finalized in December 2008, nearly two years ago. During this time, representatives from Owens-Brockway rarely participated in the SOx RECLAIM Working Group meetings or provided SCAQMD staff with any questions or feedback on the consultant's report. Only recently, SCAQMD staff received two comment letters from Owens-Brockway submitted on September 22, 2010, and on October 1, 2010. The letters contain several incorrect assumptions and technical errors relative to ETS's analysis as follows:

- The commenter incorrectly assumes that the proposed BARCT configuration relies on the continued operation of the two existing dry gas scrubbers. In actuality, ETS

[11] SCAQMD staff sent Owens-Brockway comment letter and SCAQMD staff's responses to the consultants for review, and received confirmation back that they were in agreement with SCAQMD staff's assessment. The consultants' feedback is included in this response. Emails from James Norton of NEC to Minh Pham on October 12, 2010, and Marshall Bell of NEXIDEA to Minh Pham on October 12, 2010.

proposed to remove the two dry gas scrubbers upstream of the ESPs and replace them with two new WGSs downstream of the ESPs.

- The current configuration at Owens-Brockway requires redundancy for controlling particulate emissions (via the ESPs) but not for controlling SOx emissions. Owens-Brockway currently operates two dry gas scrubbers with three ESPs connected by piping/valves, but only two ESPs are in operation at any one time while one ESP remains in stand-by mode. ETS recommended removing the two dry gas scrubbers and discontinuing the use of Trona, a very fine powder, in the two dry gas scrubbers. Doing so would be expected to reduce the particulate loading and Trona entrainment to the ESPs. Further, ETS's recommendation may substantially improve the reliability of the two on-line ESPs to the extent that the stand-by ESP may no longer be needed.

- Additional pressure drop is a concern for ALG since ALG incorrectly assumed that the BARCT control configuration recommended by ETS included both the continued operation of the two existing dry gas scrubbers and the installation and operation of two new wet gas scrubbers. Under ALG's incorrect assumption, the configuration of two dry gas scrubbers with two wet gas scrubbers would cause an additional pressure drop across the wet gas scrubbers. However, ETS recommended the removal of the two existing dry gas scrubbers upstream of the ESPs, and their replacement with two new wet gas scrubbers downstream of the ESPs so that there would be no substantial increase in pressure drop. In addition, in ETS analysis, ETS had included the costs for a system fan in the vendor's budgetary quote:

  > *"Each system comes complete with all necessary pumps, reagent storage tanks,* ***system fan*** [emphasis added]*, and stack."*

  ETS made a determination, based on their extensive knowledge and experiences with ESPs, wet gas scrubbers, and dry gas scrubbers, that the pressure drop would not be a concern in this situation. An additional fan or blower to push or pull the flue gas through the WGS would not make the control system recommended by ETS cost-ineffective.

- The three ESPs (two in operation and one in stand-by mode) were designed to ensure that if one ESP experiences operational difficulties, the stand-by ESP will take its place. ETS recommended removing the dry gas scrubbers and eliminating Trona injection. Based on this recommendation, particulate loading to the two ESPs is expected to be reduced substantially and will improve the reliability of the ESPs. ETS recommended that Owens-Brockway keep one stand-by ESP to handle upset conditions, and thus maintain the integrity of the two wet gas scrubbers downstream of the ESPs. ETS's analysis did not determine that redundancy for SOx control by adding a third scrubber would be necessary because monitoring the pH level and increasing the use of caustic may work efficiently to remove enough SOx.

- As explained above, only two WGSs would be needed. Two consultants, ETS and NEC, both identified suitable, separate locations for placement of the WGSs, Owens-Brockway is not expected to have site limitations associated with the placement of two WGSs within their facility[12].

[12] SO_x RECLAIM Study Final Report, Module 3-D: Wet/Dry Scrubbing Technology For Container Glass Manufacturing Plant, December 16, 2008, page 2.

- The commenter failed to specifically identify the foreseeable additional costs that the consultants might not have included in their analyses. ETS estimated a cost effectiveness of about $5,000 per ton SOx reduced and both ETS and NEC concurred that WGS technology is cost-effective.
- Owens-Brockway did not release any information to ETS at the site visit that could lead to a reasonably foreseeable situation that the wastewater discharge would fail the discharge limit because of selenium. Technology for treating selenium is available. The facility can treat selenium on site or can send the additional wastewater stream (10 gallons per minute) to be treated by LACSD/City of Vernon. Note that ETS budgeted $225,000 to cover the cost of wastewater treatment and this cost is included in the cost-effective calculation. ETS also provides four options to treat the wastewater stream as follows:
    1. The liquid blowdown from the scrubbers could be sent to a storage tank and recycled back to the furnaces for the batch wetting process.
    2. The blowdown could be sent to a storage tank and then to an energy efficient dryer for liquid evaporation. The solid waste could then be placed in a hopper and recycled back to the furnaces.
    3. The blowdown could be sent to a storage tank and then sprayed into the duct ahead of the precipitators to evaporate the water and collect the dry particulate in the ESPs.
    4. The blowdown could be sent to a storage tank and ran through a small skid-mounted filtration system (approximately 6 feet by 6 feet) prior to discharging to the local sanitary sewer system.
- One WGS for a FCCU has been installed and is currently operating at a refinery in the District. The exhaust gas stream from this existing WGS is expected to have similar characteristics (i.e., lower temperature, reduced plume buoyancy, caustic mist) as the proposed WGSs for Owens-Brockway. The WGS at the aforementioned refinery was evaluated to assure that it complies with all state and federal ambient air quality standards and a Permit to Operate was issued by the SCAQMD. If applications for the proposed WGSs are submitted by Owens-Brockway, the WGSs scrubbers will undergo an equivalent or similar evaluation. Moreover, with the exhaust stream entering a WGS, the NaOH would effectively disassociate to sodium and hydroxide ions, not remain as NaOH. On this basis, there is no reason to believe that here would be NaOH slip into the atmosphere.

2-26 Owens-Brockway currently holds 0.31 ton per day of RTCs and the remaining RTCs would be 0.14 ton per day after the proposed 55 percent shave. Owens-Brockway's SOx emissions in 2005 were approximately 0.2 ton per day. Owens-Brockway indicated that the control efficiency of their dry gas scrubbers was demonstrated at 90 percent, but that they are operated at 75 percent to 80 percent. If Owens-Brockway can operate their dry gas scrubbers at 90 percent, then the facility will be in compliance with the 55 percent shave since their emissions at 90 percent control would be 0.1 ton per day, below the 0.14 ton per day allocation after the shave. Under this scenario, Owens-Brockway will have surplus credits of 0.04 ton per day, which can be made available in the open market and could generate a substantial revenue stream to the company. This revenue stream could be even larger if Owens-Brockway elects to install higher efficiency WGSs.

However, if Owens-Brockway elects not to operate their dry gas scrubbers at 90 percent control, then the facility operators can purchase 0.06 ton per day (0.2 ton per day 2005 baseline – 0.14 ton per day = 0.06 ton per day) to be in compliance with 55 percent shave. The RTCs can be purchased from investors or from other SOx RECLAIM facilities that have surplus RTCs. The surplus pool has approximately 1.73 tons per day of unused RTCs in 2005, and 2.55 tons per day of unused RTCs in 2008. For these reasons, SCAQMD staff did not assume that Owens-Brockway would shut down their facility because of the proposed 55 percent shave for SOx RECLAIM.

For the above reasons, and the fact that the annual cost of compliance is estimated to be $0.52 million (Socioeconomic Report) for a facility whose parent company had net sales of $7.1 billion[13] in 2009 and a gross profit margin of 21 percent (see Response to Comment 2-2), SCAQMD staff concluded that it was not reasonably foreseeable that Owens-Brockway would shut down its facility because of the proposed 55 percent shave for SOx RECLAIM. Consequently, environmental impacts such as those mentioned in the comment are also not reasonably foreseeable, so further analysis is not required.

2-27 BARCT technology is improving over time. For example, dry gas scrubbers operating at 80 percent control efficiency were considered as BARCT in 1994. Current control technologies routinely demonstrate 95+ percent control efficiencies and can achieve control levels of 5 ppmv or better. Owens-Brockway can achieve these reductions cost-effectively. Therefore, Owens-Brockway should not be included in the list of exempt facilities in Table 5 of the PAR 2002.

2-28 SCAQMD staff and the consultants[14] disagree with ALG's technical assessment in a number of areas as explained in the following paragraphs.

- As explained in Response to Comment 2-25, the assumed configuration of the proposed BARCT to include dry gas scrubbers is incorrect. The combination of monitoring pH levels, using a sufficient amount of caustic solvent for controlling SOx emissions, and having ESPs located upstream for controlling particulate emissions would prevent excessive particulate loading and catastrophic failure to the WGSs located downstream of the ESPs.

- Since three WGSs are not required for redundancy as each can be sized to handle the entire flue gas flow from the ESPs, plot space limitations are not expected. Both consultants visited the site, evaluated the situation, and concurred that there is available plot space to located two new WGSs.

- Operational problems are site- and equipment-specific, particularly in cases where process changes are made upstream of existing systems such as in the case of the Ball-Foster facility experiencing excessive loading of particulate emissions to their

[13] O-I Announces Third Quarter Earnings Conference Calland Webcast, September 20, 2010. http://www.o-i.com/nth_us.aspx?id=400; http://www.o-i.com/about_oi.aspx?id=1348 and http://www.o-i.com/nth_us.aspx?id=400

[14] SCAQMD staff sent Owens-Brockway comment letter and staff's responses to the consultants for review, and received confirmation back that they were in agreement with staff's assessment. The consultants' feedback is included in this response. E-mails from James Norton of NEC to Minh Pham on October 12, 2010, and Marshall Bell of NEXIDEA to Minh Pham on October 12, 2010.

venturi scrubber converting their furnace to an oxy-fuel furnace. The venturi scrubber should be redesigned to handle a lower flow with higher particulate loading from the oxy-fuel furnace. As any new equipment would need to be designed for a specific installation, the design would need to take into account all operating modes and upstream conditions. Therefore, SCAQMD staff finds that the problems occurring at the Ball-Foster facility were due to the re-use of existing control equipment instead of redesigning the controls, and these problems would not be expected to apply to the Owens-Brockway facility. In addition, Owens-Brockway has three ESPs located upstream of the scrubbers to control particulate matter which will help prevent excessive buildup of particulate emissions in the WGSs.

- Dry gas scrubbers operating at 80 percent control efficiency are no longer considered BARCT because current state-of-the-art systems can reliably achieve 95 percent or more SOx reductions and achieve SOx emission levels of 5 ppmv or lower. SCAQMD staff, therefore, recommends the BARCT level for glass melting furnaces to be 5 ppmv. However, if the dry scrubbers are operated at 90 percent efficiency, then Owens-Brockway should be able to comply with the proposed RTC shave.

2-29 Regarding the suggestion to clarify the language in subparagraph (f)(1)(Q) of Rule 2002, SCAQMD staff disagrees with the commenter's proposed interpretation. The intent of this subparagraph is that any facility entering the RECLAIM program after the date of adoption and that operates the basic equipment in Table 4 shall have its SOx allocations determined according to the BARCT level listed in Table 4 or the permitted emission limits, whichever is lower. Existing facilities that operate the basic equipment listed in Table 4 will have their allocations adjusted in accordance with Rule 2002, subparagraphs (f)(1)(I) and (f)(1)(J) at the Table 4 BARCT levels, effective 2012. It should be noted that all Table 4 equipment in existing non-RECLAIM facilities have achieved the proposed BARCT standards (e.g., diesel combustion). This clarification will be made in the proposed amended rule and Staff Report.

2-30 SCAQMD staff's responses to the individual comments are summarized as follows, but because of overlapping concepts in several bulleted items, the order of the responses does not necessarily directly correspond to the order of each bulleted item in the comment letter:

- The 2005 reported emissions for Owens-Brockway's glass furnaces were approximately 0.2 ton per day with their dry gas scrubbers typically operating in the range of 75 percent to 85 percent control efficiency, but occasionally achieving a control efficiency as high as 90 percent. The background on Owens-Brockway's furnaces and control equipment provided in the comment is consistent with this 2005 emissions data and the information documented by ETS (i.e., testing on the dry gas scrubbers demonstrated up to 90 percent control efficiency). If the dry gas scrubbers were operated consistently at a 90 percent control efficiency level, then Owens-Brockway would emit approximately 0.1 ton per day and as such, would be in compliance with the proposed 55 percent shave without additional control.

- SCAQMD staff knows of no installation in which a facility relies upon using dry gas scrubbers, dry ESPs, followed by wet gas scrubbers to achieve the emission reductions recommended by the consultants. However, based on the consultants' reports, SCAQMD staff believes that the level of 5 ppmv SOx (which represents a 95

percent control efficiency or more) can be achieved in practice, is cost-effective and is not expected to create the severe problems alleged by the commenter's technical assessment.

The proposed BARCT level for glass melting furnaces has been achieved in practice. Specifically, the Puget Sound Clean Air Agency in Seattle, Washington, provided SCAQMD staff with source test and CEMS data that demonstrates compliance with 5 ppmv SOx levels at 96 percent control efficiency via Tri-Mer's Cloud Chamber scrubber for a furnace with a permit limit of 1.6 pound of SOx per ton of glass pulled but tested at 0.0062 pounds of SOx per ton of glass pulled[15, 16]. SCAQMD staff was provided with supporting documentation from Tri-Mer and other WGS vendors that demonstrated that the Cloud Chamber scrubber as well a packed bed scrubber, venturi scrubber, or open throat type of scrubber can be used to achieve 5 ppmv SOx level when appropriately designed and operated.

There are several types of WGSs that can be considered for the Owens-Brockway facility: 1) quench, vertical packed bed scrubbers as recommended by Manufacturer A; 2) simple open-throat scrubbers as recommended by Manufacturer D; or, 3) fluidized rotating scrubber as offered by Manufacturer B. NEC recommended Manufacturer D's open-throat type and ETS recommended Manufacturer A's packed bed scrubber. Manufacturer A indicated that the packed bed scrubber can tolerate up to 20 micrograms per cubic nanometer (µg/nm3) of insoluble particulate without clogging; and if the particulate is soluble (e.g., sodium sulfate), then the packed bed scrubber would not have a problem with plugging[17]. The SOx RECLAIM program does not require Owens-Brockway's operators to install any particular type of scrubber. In fact, Owens-Brockway's operators are encouraged to study their options further and research the type of WGSs and solvents that best fits their operation and emission profiles.

- The control configuration recommended by ETS (which was proposed by Manufacturer A) consists of three existing ESPs followed by two new WGSs. Manufacturer A and ETS recommended the removal and replacement of the two existing dry gas scrubbers with two WGSs downstream of the three existing ESPs. Further, the commenter incorrectly assumes that three WGSs would be needed to correspond with the three ESPs units. Even though the three ESPs are connected by piping/valves, only two are in operation at any one time and the one remains in standby mode. Thus, there is no need to install three WGSs when there are only two operational ESPs at any one time. For these reasons, ETS recommended replacing the two existing dry gas scrubbers with two new WGSs. Further, because the analysis is based on the replacement of the two existing dry gas scrubbers with two new WGSs, and not three WGSs as suggested by the commenter, the cost-effectiveness analysis only includes the costs associated with the installation and operation of two new WGSs downstream of two existing ESPs. Also, because ETS recommended the removal of the two existing dry gas scrubbers, the cost-effectiveness analysis does not

[15] Horizon Engineering, "Source Test Evaluation Report for Saint-Gobain, Seattle, Washington, Glass Melting Furnace No. 5 with Cloud Chamber Scrubber," September 18, 2009.
[16] CEMS Summary Report from Saint-Gobain to Puget Sound Clean Air Agency, for a period from October 1, 2009 to October 31, 2009.
[17] Email from Manufacturer A to Minh Pham – Solution Based Absorbents for Scrubbers, January 29, 2010.

and should not be based on the continued operation of the dry gas scrubbers in addition to the two WGSs.

- Regarding the sizing of the two WGSs, since each of Owens-Brockway's ESPs operates at a capacity of 30,000 acfm, or at combined capacity of 60,000 acfm with one ESP in stand-by mode, then the combined capacity of the two WGSs would also need to be sized at 60,000 acfm, not 90,000 acfm as suggested by the commenter. However, Owens-Brockway operators may choose to build a larger system for redundancy (e.g. 90,000 acfm instead of 60,000 acfm). A larger system will cost more but it will not make the BARCT recommended by the consultants become cost-ineffective (i.e. larger than $50,000 per ton) since the cost-effectiveness for the 60,000 cfm system was estimated to be $5,000 per ton, and the capital costs are proportional to the $(90{,}000/60{,}000)^{\exp 0.6} = 1.28$ factor.
- As explained in Response to Comment 2-25, additional pressure drop was a concern for ALG since ALG incorrectly assumed that the BARCT control configuration recommended by ETS included both the two dry gas scrubbers and the two wet gas scrubbers. However, ETS recommended the removal of two dry gas scrubbers upstream of the ESPs, and replace those with two WGSs downstream of the ESPs. Also, Manufacturer A included a fan in their proposal. Therefore, the manner in which the equipment could be configured should remedy any concerns of pressure drop across the system.
- The commenter incorrectly assumes that Trona will still be needed even though ETS recommended stopping the use of Trona and replacing the two existing dry gas scrubbers upstream of the ESPs with two new WGSs downstream of the ESPs. Removing the dry gas scrubbers and eliminating the use of Trona would substantially reduce the particulate loading to the ESPs. Further, as is the case with current operations at Owens-Brockway, if an ESP goes offline, the stand-by ESP would become operational so that only two ESPs would be operational at any time. Thus, there would be no extra loading to the WGSs in the event an ESP goes off-line. Overall, this configuration would reduce the loading to the WGSs downstream of the ESPs.
- The suggestion that the WGS proposed by ETS is under-sized because the particulate loading allowed by the permit (0.08 grains/dry standard cubic feet) is an order of magnitude higher than the amount assumed by ETS (0.008 grains/dry standard cubic feet) represents a misunderstanding about what data is considered when sizing a WGS. The capacity or size of a WGS is dependent upon several factors. ETS provided the vendors with flue gas flow rates, inlet concentrations, and other necessary parameters so that the manufacturers could estimate the size and associated costs of the WGS. Because flue gas flow rate, not particulate loading, is the critical parameter that was used to determine the equipment costs and the size of the WGS, the WGS recommended by ETS would be able to handle the permitted particulate loading (0.08 grains/dry standard cubic feet).
- Owens-Brockway reported that the facility is currently sending wastewater to the LACSD and the City of Vernon to be treated at a rate of 41.89 million gallons per year which equates to approximately 80 gallons per minute (gpm). Owens-Brockway has a maximum discharge limit of 131.4 million gallons per year or 250 gpm. The increase in discharge due to the two WGSs is 10 gpm which is expected to mainly contain soluble sodium sulfate that would result from using caustic solvent as the

scrubbing agent. With an additional discharge of 10 gpm, Owens-Brockway is far below their permitted threshold of 250 gpm. In addition, on October 26, 2010, following SCAQMD staff's request, Owens-Brockway provided SCAQMD staff with their facility's industrial wastewater discharge permit issued by the LACSD which shows that currently LACSD has effluent concentration limits for arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, zinc, cyanide, and total dissolved sulfides. There is no effluent discharge concentration limit for selenium on Owens-Brockway's industrial discharge permit. Furthermore, SCAQMD staff estimated the concentration of selenium that could potentially be present in Owens-Brockway's wastewater stream based on their annual emission reports from 2002 to 2009. Selenium concentrations in their wastewater stream was estimated to be around 0.022 mg/L[18], much less than the thresholds set in the Code of Federal Regulations(CFR), Part 268 – Land Disposal Restrictions for wastewater and non-wastewater. For these reasons, SCAQMD staff believes that both the LACSD and the City of Vernon will be able to receive and treat an additional 10 gpm waste stream that contains trace amounts of selenium and other inorganic compounds.

The consultant (ETS) also allocated $225,000 into the scrubber equipment cost estimate for handling the waste stream from the scrubbers (e.g., selenium). The $225,000 estimate was based on information provided by Manufacturer D which has expert knowledge of WGS technology and WGS effluent waste treatment. The estimate was also based on relevant experience with the waste stream from a glass manufacturing facility located in Seattle, Washington[19]. In addition, ETS, in their final report, provided four options for Owens-Brockway to treat the waste stream onsite:

1. The liquid blowdown from the scrubbers could be sent to a storage tank and recycled back to the furnaces for the batch wetting process.
2. The blowdown could be sent to a storage tank and then to an energy efficient dryer for liquid evaporation. The solid waste could then be placed in a hopper and recycled back to the furnaces.
3. The blowdown could be sent to a storage tank and then sprayed into the duct ahead of the precipitators to evaporate the water and collect the dry particulate in the ESPs.
4. The blowdown could be sent to a storage tank and ran through a small skid-mounted filtration system (approximately 6 feet by 6 feet) prior to discharging to the local sanitary sewer system.

Lastly, since technology for selenium treatment is available, SCAQMD staff recommends that Owens-Brockway operators conduct their own evaluation of these recommended options to find an appropriate method to treat any selenium in the WGS wastewater. There are no significant environmental impacts expected with the options quoted above. While the commenter criticized Option 3 (the comments were based on the incorrect assumption about the continued use of dry gas scrubbers and Trona injection), no comments were submitted relative to Options 1, 2 and 4.

[18] Email from Kevin Orellana to Minh Pham on October 26, 2010.
[19] Email from ETS, Inc. to Minh Pham on October 27, 2010.

- Regarding the comment about moisture build-up/clogging in the ESPs, see Responses to Comments 2-3 and 2-28.
- There are hundreds of scrubbers operating across the nation that currently utilize caustic solution (NaOH, 50 percent by weight) as a scrubbing agent. The commenter has failed to provide evidence to support the claim that the use of caustic solution will create additional environmental impacts, other than what was already identified and analyzed in the Draft PEA. Further, as mentioned in Response to Comment 2-15, there is no evidence for the potential of NaOH slip from a WGS. The application of the Rule 1401 screening emission level would be justified if there were any indication of NaOH emissions. In fact, with the exhaust stream entering a WGS, the NaOH would effectively disassociate to sodium and hydroxide ions, not remain as NaOH. Thus, there is no reason to believe that the use of caustic in a WGS would emit NaOH slip into the atmosphere.
- Regarding compliance with the new federal NO2 standard, see Response to Comment 2-13.
- The commenter refers to the Green Chemistry Initiative and suggests that the use of NaOH may be inconsistent with its requirements. The "Green Chemistry Draft Regulation for Safer Consumer Products[20]" is a draft regulation prepared by California Department of Toxic Substances Control (DTSC) that specifies the processes for DTSC to scientifically and systematically identify and prioritize chemicals and consumer products, for manufacturers to conduct alternatives assessments, and for DTSC to impose regulatory responses for alternatives selected by manufacturers.

  According to the draft regulation, the term "Green Chemistry Principles" means: 1) prevention of waste rather than treating it or cleaning it up; 2) incorporation of all materials used in the manufacturing process in the final product; 3) use of synthetic methods that generate substances with little or no toxicity to people or the environment; 4) design of chemical products to be effective, but reduce toxicity; 5) phase-out of solvents and auxiliary substances when possible; 6) use of energy efficient processes, at ambient temperature and pressure, to reduce costs and environmental impacts; 7) use of renewable raw materials for feedstocks; 8) reuse of chemical intermediates and blocking agents to reduce or eliminate waste; 9) selection of catalysts that carry out a single reaction many times instead of less efficient reagents; 10) use of chemicals that readily break down into innocuous substances in the environment; 11) development of better analytical techniques for real-time monitoring to reduce hazardous substances; and, 12) use of chemicals with low risk for accidents, explosions and fires.

  While NaOH, a toxic air contaminant (TAC) that is a non-cancerous but acutely hazardous substance, is a very common scrubbing agent, it is not the only solvent that can be used in Manufacturer A's scrubber. However, for a worst-case analysis in the Draft PEA, the use of NaOH was assumed. Thus, if Owens-Brockway operators choose to install WGSs and apply the draft Green Chemistry Principles to their choice of solvent for the WGSs, soda ash, a non-toxic, non-cancerous, and non-hazardous substance, could be utilized instead as an alternative scrubbing agent.

[20] http://www.dtsc.ca.gov/PollutionPrevention/GreenChemistryInitiative/upload/Safer-Product-Alternative-Regulations-6-23-10.pdf

- While there may not be sufficient space for three WGSs, only two scrubbers were recommended by the consultants (ETS and NEC) with input from Owens-Brockway's operators as explained in Response to Comment 2-25. Both ETC and NEC were in agreement that three WGSs are not needed to handle the entire flue gas flow (60,000 acfm) from the two ESPs and that the facility had sufficient space for siting two WGSs. Thus, there is no need to find space for a third WGS.

- Regarding the comment relative to siting the control equipment, the consultants identified two different potential locations at the site for the WGSs. While the specifics of the potential locations are confidential at the request of the facility operators and cannot be disclosed in this response, the confidential details have been provided to Owens-Brockway personnel. What can be disclosed in this document, however, is ETS's general description of the plot space availability at the Owens-Brockway facility:

  > *"The plant has limited space available for additional equipment, approximately a 14' x 20' footprint between two existing scrubbers. In addition O-I personnel indicated that the height of any new equipment could not exceed 30 feet above the top of the existing scrubbing vessels. A request was made of O-I to provide us with dimensional information pertaining to available space for the Manufacturer A equipment footprint.* ***They stated that there is space available*** [emphasis added]. *Horizontal distance is 63' depending on the location of the ducting out of the pieces of equipment. This does not take into account the vertical distance which will depend on location of entry to the stream*[21]*."*

  In addition, NEC's general description of the plot space availability is as follows:

  > *"We located an elevated area just to the west of the ESP's* [sic] *and adjacent to the existing ammonia storage tank where Facility D felt the unit could potentially be located. This new area is located above an existing truck turnaround area*[22]*."*

  Neither ETC's nor NEC's reports reflect any suggestions from Owens-Brockway's representatives that the WGSs would need to be sited in a parking lot or that an existing structure would need to be torn down. In the context of the comment, it seems that the commenter is suggesting these circumstances based on the misunderstanding that a third WGS would need to be installed. SCAQMD staff continues to assert that two WGSs sufficiently sized can provide the necessary capacity to ensure compliance with the proposed BARCT for glass melting furnaces. See also Responses to Comments 2-25 and 2-28.

  For these reasons, SCAQMD staff continues to believe that there is sufficient space at the Owens-Brockway facility to site two WGSs. Further, the costs associated with the siting options proposed by the consultants have already been included in the cost-effective and socioeconomic analyses. See also Response to Comment 2-2.

- The ETS analysis included all of necessary costs. However, NEC recommended raising ETS's costs to include contingencies, costs for additional ducting and valves

[21] SO_x RECLAIM Study Final Report, Module 3-D: Wet/Dry Scrubbing Technology For Container Glass Manufacturing Plant, ETS Inc., December 16, 2008, page 2.

[22] SOx RECLAIM BARCT Capital & Operating Cost Review – Final Report – Non-Confidential, NEC Inc., May 28, 2010, page 12.

for an alternative location. The commenter indicated that additional costs for CEMS upgrade were also needed. This additional cost would be covered by NEC's recommended cost adjustment for contingencies. By including all of the additional costs suggested by NEC, which would cover the cost for the CEMS upgrade, the BARCT recommended by ETS would remain cost-effective. Even with the adjustments made to ETS's initial cost estimates, NEC concurred that the control costs for WGSs would be cost-effective for glass melting furnaces.

- With regard to the comment about the technical data that was relied upon to support a 25-year useful life of a WGS, a leading manufacturer of WGSs provided the SCAQMD staff with a confidential list of all its wet scrubbing systems installed worldwide. In this list, there were 20 wet gas scrubber installations that are 25 years or older and still operating. For this reason, SCAQMD staff applied a 25-year useful life assumption for WGSs.
- Regarding the implementation challenges face by the Ball-Foster facility, see Response to Comment 2-3.
- Regarding the proposed BARCT level and how it relate to the emissions at glass plant located in Seattle, Washington, see Response to Comment 2-4.

Subject: WSPA Comments on SCAQMD SOx RECLAIM Draft Program Environmental Assessment (DPEA)

Sent on behalf of Catherine Reheis-Boyd.

Dear Ms. Radlein:

Please see attached Western States Petroleum Comments on the SCAQMD SOx RECLAIM Draft Program Environmental Assessment (DPEA). If you have any questions, please call Cathy at (916)498-7752 or email: cathy@wspa.org.
Thank you.

Dear Ms. Radlein:

SCAQMD SOx RECLAIM Draft Program Environmental Assessment (DPEA)

Attached are the Western States Petroleum Association's (WSPA's) comments related to the Draft Program Environmental Assessment (DPEA) for proposed amendments to Regulation XX, the RECLAIM SOx shave. WSPA is a non-profit trade association representing twenty-eight companies that explore for, produce, refine, transport and market petroleum, petroleum products natural gas and other energy products in California and five other western states.

WSPA member companies operate petroleum refineries, distribution terminals and other facilities in the South Coast Air Basin. WSPA has been involved in air quality issues in California and the South Coast for 40 years. We pioneered the use of computerized modeling, and sponsored some of the first regional air quality monitoring programs that documented ambient air quality and the impacts of atmospheric emissions. 3-1

The RECLAIM Work Plan that was initiated in January 2010 identified environmental impacts and substantial cost factors associated with this regulatory proposal. WSPA made a commitment to follow the Work Plan in January 2010. We continue to be responsive and transparent in working with the District staff.

As an outgrowth of the work plan, and in an effort to understand the basis for our differing views concerning the costs and environmental benefits of various reductions in RTC allocations, staff from WSPA and the District have recently begun development of a clear and concise cost summary. That cost summary identifies the policy choices facing industry and the District. 3-2

If this effort is successful, we see development of the summary as an important first step in informing the SCAQMD Board in preparation of the upcoming adoption hearing. We will keep you informed of our collective progress.

cathy@wspa.org • www.wspa.org

As part of our ongoing effort to work with the District and balance environmental impacts with costs, WSPA first proposed a 25% shave. Then, using alternative methodology we presented a 33% shave proposal. WSPA recently increased our proposal to a 40% shave.

The estimated costs to the refining industry for the 40% proposal are still over half a billion dollars. This represents a huge commitment from the refining industry to support the District's efforts to reduce emissions. Despite our proposal the District's position remains unchanged at a 55% shave with an estimated cost to the refining industry of over $1.5 billion.

WSPA's proposal exceeds all applicable local, state, and federal regulatory requirements for this proposed rule making. WSPA believes the District should accept our proposal or bring forth a more realistic and reasonable proposal than the current 55% shave – one that balances the clean air obligations of the District with the economic health of the region and the refining industry.

3-2 Cont'd

Background

As currently proposed, the amendments to Regulation XX rely heavily on the control of industrial facilities including several refinery source categories. WSPA has reviewed all the SCAQMD reports by consultants and District staff, and provided feed back to the District staff.

Detailed comments for the District's 55% proposal are provided in the attachment; however, the DPEA only partially addresses some of the impacts and cost issues. Our attached comments note deficiencies in areas where additional critical analyses should be done. We would like to highlight the following:

3-3

1. RTC Market Analysis

   The DPEA concludes that the current shave proposal will not result in constraints to the RECLAIM market and states: "there will be sufficient SOx RTC's available to maintain trading within the SOx RECLAIM program." This statement has not been substantiated by any analysis conducted as a part of the DPEA or any other document available for review to date.

   The SCAQMD arrived at this conclusion before the socio-economic or market impacts studies have been concluded. District Staff needs to conduct an analysis and make it available to the public for review and comment so that it may inform the Board's decision.

3-4

2. Cost to Comply

   WSPA has repeatedly informed the District that the estimated compliance costs are underestimated substantially. The District's consultants' estimates failed to consider the project scope including, but not limited to space limitations, additional utility infrastructure and the practical limitations placed on working refineries. The depth of the proposed shave will drive compliance costs far beyond any reasonable level and exceeds acceptable cost effectiveness thresholds.

3-5

1415 L Street, Suite 600, Sacramento, California 95814
(916) 498-7752 • Fax: (916) 444-5745 • Cell: (916) 835-0450
cathy@wspa.org • www.wspa.org

WSPA agrees with the conclusion of the District's consultant Norton Engineering that the cost effectiveness analysis needs improvement. The Norton Engineering Report documented various deficiencies in the analysis of five out of six source categories.

The Report encourages the District to re-calculate the cost effectiveness analysis for the affected source categories; however, the District has refused to follow the recommendation of its consultant and recalculate the cost effectiveness.

The District's overly aggressive proposal incorporates the seizure of "unused" RTC's in a manner that doubles the compliance cost. The costs to achieve emission reductions required by the proposed shave are nearly double the costs required to achieve emission reductions equivalent to installation of BARCT controls on refinery sources.

The DPEA should expressly evaluate the costs of achieving BARCT levels of emission reductions. We note that this approach was partially discussed as Alternative C; however, that did not expressly discuss the implications for not confiscating an additional 1.75 TPD in RTC's.

3-5 Cont'd

3. The DPEA concludes the cumulative mitigation measures for water supply and green house gas (GHG) emissions are insufficient to mitigate impacts below the level of significance. This finding requires the District to adopt a statement of over-riding consideration in order to certify the DPEA findings. Because of this fact, it seems appropriate that the District consider an alternative that is less environmentally adverse.

3-6

4. The District's DPEA notes that Alternative C poses fewer environmental impacts and may not require a statement of over-riding consideration for either water or GHG mitigation. The District should specifically address why Alternative C was not selected as this would satisfy all current local, state and federal regulatory requirements.

3-7

5. The District's Norton Report notes that technologies identified as BARCT for cement plants and acid plants are neither typical installations nor appropriate for identification of BARCT. The DPEA should revisit the identification of BARCT and correct errors associated with the Staff Report, and should document the resulting consequent changes in the environmental impacts.

3-8

6. The DPEA is insufficient in scope to support the permitting of required equipment and related processes as companies prepare to meet compliance objectives. Key issues such as New Source Review (NSR), Prevention of Significant Deterioration (PSD) and offsets, are not addressed. Mitigation measures have not been documented sufficiently and the analysis of these impacts may not be sufficient to support applications submitted in support of projects proposed to achieve the required shave levels.

3-9

WSPA is committed to working with the SCAQMD to facilitate a constructive SOx rule making that will result in meeting the necessary environmental objectives at a cost that will not economically damage the region or the refining industry. We have negotiated in good faith, moving from an initial position of a 25% shave to our current 40% shave position, which results in 4.7 TPD of actual reductions.

3-10

1415 L Street, Suite 600, Sacramento, California 95814

cathy@wspa.org • www.wspa.org

Since this DPEA will be used to support permitting and actual project implementation, it is vital that the environmental impacts and mitigation measures adopted are based on an accurate and complete body of evidence.

WSPA supports the 2007 AQMP analysis and related emission reduction targets, but with a BARCT adjustment that is based on a complete and accurate technological and cost effective determination. This in-turn requires a sound environmental impacts analysis, based on realistic compliance assumptions.

Page A-1

ATTACHMENT A: GENERAL COMMENTS

Overall

Comment: The District should have analyzed environmental impacts of seizing the "unused" RTCs. These are NOT unused, but are necessary for the facilities to ensure compliance with the existing rule and avoid having to purchase RTCs in an adverse market. In addition, a market for RTCs gives facilities flexibility when implementing compliance options and at the end of each cycle. WSPA requests that the District analyze the impact of a highly constrained market on key environmental factors such as air emissions, GHG emissions and water use. 3-12

Comment: The District should have re-calculated the cost-effectiveness for all technologies because of the Norton Report's findings. The District should, in particular, recognize that there were major edits in 5 of the 6 source categories reviewed by Norton Engineering. WSPA requests that the updated cost-effectiveness calculations be included in the Programmatic Environmental Assessment (PEA). This evaluation is critical to understanding the environmental impacts of the proposed project and identified alternatives. 3-13

Comment: The DPEA did not adequately address the possible need for additional water supplies or the costs for and reliability of the supply of the additional water needed. For example, given the current restrictions in the supply of potable water, the DPEA makes reference to the substitution of recycled water.

However, the expanded use of recycled water was not carefully evaluated. For example, costs associated with building the needed infrastructure to the facility, infrastructure within the facility, expansion and operation of the process water treatment plant, cost of the recycled water itself, and cost of waste water handling were not discussed in any detail. Another critical issue not addressed is the reliability of the recycled water source and delivery infrastructure. Refinery process units are 24/7 operations, requiring the same level of dependability from any utility required to operate related emission control equipment.

In order to prepare a complete PEA, the District should expand its analysis of water and wastewater use and handling (see Attachment B, Comments 1-3 and 1-5). 3-14

BARCT Technology

Comment: A comprehensive discussion of De-SOx technology feasibility and control effectiveness – which are highly unit-specific – is necessary. In addition, De-SOx additives have the effect of diluting the circulating cracking catalyst and potentially adversely impacting conversion within the FCCU. Such a reduction of cracking effectiveness would have a significant adverse economic impact on a refinery. 3-15

Comment: No "dry alternative" is considered. The District, in order to evaluate the full range of options, should consider Alternatives that do not include use of a Wet Gas Scrubber. We note, for example, that even Alternative C features use of four scrubbers. 3-16

Comment: The District claims (page 2-6) that there are "three main strategies that can be employed" to reduce SOx emissions from SRU/TGUs - 1) increase the efficiency of the SRU, 2) improve the efficiency of the TGU, and 3) install a wet gas scrubber. WSPA notes that so-called strategies 1 and 2 are not strategies at all but, rather are 3-17

1

general and non-specific objectives. The District goes on (Table 2-2, page 2-10) to suggest that a candidate BARCT technology for SRUs would be the use of a selective oxidation catalyst. Such catalysts, to WSPA's knowledge, have never been used in an SRU and, consequently, cannot be deemed a viable option. Further, if staff is going to consider this technology, the possible impacts to air emissions, energy use and water consumption as well as an updated cost analysis also need to be considered. 3-17 Cont'd

Comment: To consider a WGS for the calciner, the District must recalculate the cost effectiveness with Norton's updated numbers. This recalculation will help inform the decision on the comparative impacts of various control strategies on water, electricity use and air emissions. 3-18

Comment: The District failed to consider the reasonable worst-case scenario of no additional recycled water supplies dedicated to the RECLAIM facilities. As noted in Comment 1-3 and 1-5 in Attachment B, it is quite possible that the facilities will have no access to new supplies or future increases in the supply of recycled water. The current analysis is insufficient for both the "most likely" and "mitigated" scenarios. Thus the conclusions on P 5-83 are unsupported by the analysis. 3-19

Comment: Table 4-1 indicates that a 5 ppm SOx level can be achieved on FCCUs by using De-SOx catalyst. Yet, no underlying data are provided to show this to be the case. If the District is now asserting that 5 PPM SOx level can be achieved by De-SOx catalyst, then this data should be presented as part of the Final PEA because this option may have significant implications on energy use, water use and emissions compared to other alternatives. 3-20

Comment: The District Staff states (pages 2-5 and 6) that their consultant determined that utilizing a wet gas scrubber for process heaters or boilers would not be cost-effective, but that refineries can "opt" to use lower sulfur-containing fuels in order to reduce SOx emissions from these combustion sources. This assertion is inaccurate.

Fuel gas sulfur content can only be reduced to the extent allowed by the capacity of a facility's fuel gas treating system. Further, the refinery's sulfur plant has to have the capacity to process the additional sulfur that would be removed from the fuel gas. A detailed analysis of the effort required to reduce sulfur emission is essential for a complete PEA. WSPA encourages an expanded review of the costs, environmental impacts and resource commitments associated with various sulfur control technologies. 3-21

Comment: The District claims (page 2-13) that the sulfur content of refinery fuel gas may be further reduced to a range between 25 ppmv and 35 ppmv and the outlet SO_x concentrations from refinery boilers and process heaters may also be limited to less than 20 ppmv by implementing "efficiency improvements" to fuel gas treatment systems. However, the District does not provide any data to support this contention or any analysis to support their conclusions.

There is no information provided about cost effectiveness of such "efficiency improvements." Some refineries included fuel gas treatment options in the WSPA cost survey and the District is aware of this. But, any such treatment enhancements are not necessarily applicable or cost effective for every refinery. While not a part of the BARCT adjustment, if the District wishes to include this approach within the PEA, it would seem appropriate to conduct more site-specific analyses. 3-22

BARCT Definition

Comment: The Health and Safety Code specifically defines BARCT as "…best available retrofit technology means an emission limitation that is based on the maximum degree of reduction achievable taking into account environmental, energy and economic impacts by each class or category of source." Because of the significant water demand impacts of the proposed rule, a "dry" technology alternative should be included in the DPEA. Currently, Alternative C contemplates a reduction in the number of categories subject to wet gas scrubber technology. 3-23

Draft Rule and Calculated Emission Reductions

Comment: Regarding paragraphs (f)(1)(N) and (M) of the rule, the $50,000/ton threshold should be based on perpetuity credits, not single year credits, because perpetuity credits are more reflective of long-term compliance costs. The price of single year credits would just depend on whether a facility had excess credits during that particular year due to, for example, a turnaround. 3-24

The single year credit cost is not directly related to the true cost of controls. This aspect of the rule should be addressed as part of the PEA and the Socioeconomic Report that must be prepared to inform the Board in its deliberations.

Draft Rule Emission Reductions

Comment: The emission reductions shown in the table below are still too aggressive, particularly in terms of feasibility concerns and significant environmental impacts. Tonnage in the table is based on the schedule for emission reductions in the Proposed Project. The tonnage and emission reduction schedule should be provided for all Alternatives.

For example, the DPEA should consider the environmental impacts of a less aggressive reduction such as 1 TPD each year for the first 3 years and then 0.4 TPD from 2015 - 2019 for a total of 5 tons by the end of 2019. 3-25

Year	Pounds/yr	Tons/yr	Cumulative Tons/Day	Incremental Yearly Ton/Day Reduction
2012	1,095,000	547.5	1.5	1.5
2013	2,190,000	1095	3	1.5
2014	3,285,000	1642.5	4.5	1.5
2015	3,518,600	1759.3	4.82	0.32
2016	3,752,200	1876.1	5.14	0.32
2017	3,985,800	1992.9	5.46	0.32
2018	4,219,400	2109.7	5.78	0.32
2019 and after	4,453,000	2226.5	6.1	0.32

ATTACHMENT B: MAJOR COMMENTS

EXECUTIVE SUMMARY (CHAPTER 1)

SCAQMD's response to the controversy in the amount of the SOx shave as indicated in Table 11 on page 1-11 of the DPEA is as follows: "…the rule analysis shows that after the shave is imposed, there will be sufficient SOx RTCs available to maintain trading within the SOx RECLAIM program."

> **Comment 1-1**: The District has not provided any analysis in its DPEA to support this statement. This is especially important because the current SOx market is very "thinly traded" with a limited number of participants. Hence it seems important that the District assess the environmental impacts if, as has occurred in other emission trading programs, SOx market trading is distorted or impaired due to the proposed shave and seizure of currently "unused" RTCs.
>
> Moreover, the assertion that there will be sufficient RTCs available to maintain trading within the program after an aggressive shave in RTCs has not been substantiated by fact. In fact, there is no way for the District to predict, with any certainty, future market response to reductions in the RTC market consistent with the proposal, nor has the possibility for significant environmental impacts associated with an aggressive shave in RTC reductions been analyzed. The District must more fully evaluate the range of possible impacts to the RECLAIM market resulting from various shave levels.
>
> The SOx market is much more constrained in terms of market participants and trading, so any "lessons learned" from the NOx market may not be applicable. Thus, the PEA should consider and evaluate impacts due to market instabilities that are more likely in a constrained credit situation such as the current proposed rule.

3-26

In the DPEA, SCAQMD states (Table 1-1; P. 1-12), "According to both of the consultants' reports, a facility-by-facility evaluation was conducted which included an analysis of plot space availability. The analysis does not support the claim that there is not adequate plot space available to install SOx controls." While we understand that the District's consultants were instructed to look at control technology, it seems clear that key issues such as plot space and the requirements of a functioning refinery were not given adequate weight.

Design and layout of control technology including construction and installation needs are important constraints that must be considered. If the District's assumptions on layout are incorrect, it could mean that a lot more construction must be done which will have greater impacts. The District Staff should revisit their assumptions and environmental requirements associated with their proposed control technologies.

3-27

Comment 1-2: While companies will answer individually, it is clear that plot space limitations and related infrastructure requirements documented by company operators are both real and unaddressed. The PEA should analyze the impacts of actual plot space needs.

> We disagree with the Staff assertion that "the contractor analysis does not support the claim that there is not adequate plot space available to install SO_x controls." For example, the Norton Engineering Report (NE) cites examples where the location of proposed equipment needs to be modified due to operations needs [see p. 8-9]. Moreover, the collective experience of the refineries and their respective engineering contractors to design, construct, and operate refinery equipment is greater than that

3-28

associated with consultants retained to simply look at feasibility. Again, flawed assumptions relating to space requirements can adversely impact the analysis of construction costs and operating requirements.

3-28 Cont'd

"With regard to water demand impacts, SCAQMD staff recognizes that wet gas scrubber technology is water intensive. However, recycled water can be used in lieu of potable water. Specifically, up to 75 percent of the estimated increase in water demand due to the wet gas scrubbers under Option 1 of the proposed project can be satisfied with recycled water." [p. 1-13]

Comment 1-3: These statements are misleading. Although it is true that recycled water could likely be used in lieu of potable water, this can occur only if there is sufficient supply and infrastructure to supply the water to the affected facilities. The district must also consider whether building the additional infrastructure is feasible, both physically and economically.

Specific issues that need to be considered are: 1) the existence of a reliable supply of recycled water available to each facility 2) the existence of infrastructure, internal to each facility, to provide recycled water to the processes that would use the water 3) the capital cost to build the necessary infrastructure if it does not already exist and 4) to have a supply of recycled water available for use within the timeframe required for compliance.

3-29

Currently 8 out of 11 affected facilities "do not have access to recycled water" (see p. 3-67 in DPEA). While water purveyors are looking into the possibility of providing additional recycled water (i.e., the Harbor Refineries Recycled Water Pipeline Project (HRRWPP)), this does not necessarily mean that the specific RECLAIM facilities will have access and/or rights to it, or that water can be supplied in sufficient volumes.

The Staff should also analyze this issue on the basis that 8 of the 11 affected facilities have no current access to recycled water (see also comment 1-5 below).

"Implementation of the proposed project is expected to span over seven years, which should be adequate time for purchasing and installing wet gas scrubbers." [p. 1-14]

Comment 1-4: This assumption is speculative and leads to the underestimation of environmental impacts. While it is true that companies would tend to defer the more costly investments to the future, it is not clear that it would be the case for most companies. In fact, given the very aggressive reductions required in the first 3 years, and the uncertainty in the market, companies may need to reduce emissions in the short term – leading to high capital investments early in the compliance period rather than later as the District expects.

3-30

The District should evaluate a range of construction and installation schedules that vary from installation within 3 years to installation through the end of 2019.

"For water demand, there are three significance thresholds based on whether: 1) the total water demand of the proposed project is less than five million gallons per day 2) the existing water supply has the capacity to meet the increased demands of the proposed project and, 3) the potable water demand is a substantial use of water. The analysis shows that the increased potential demand for total water that may result from implementing the proposed project is not expected to exceed the significance threshold of five million gallons of total water demand per day.

3-31

Further, based on discussions with the local water suppliers, the existing water supply is expected to have the capacity to meet the increased demands of the proposed project. However, because the entire state of California is in the midst of a severe drought, a water supply analysis relative to the current and future availability of potable water and the use of recycled water and industrial-use groundwater to satisfy some of the water demand needs of the proposed project was conducted." [p. 1-24]

Comment 1-5: In analyzing the impact for CEQA, the district should analyze the worst-case scenario, which is that the demand would be on the potable water supply. While such an analysis could mean that the technology would become infeasible, the District must conduct a realistic environmental assessment and should not attempt to choose assumptions simply to justify its rule options.

Although the District does conclude by determining that potable water demand impacts are significant, the District Staff's summary of environmental impacts is inadequate given their review of the current water shortage in the State as described below: "However, back-to-back dry years and low reservoir levels have put California in a statewide drought. In late 2008, the state's major reservoirs were at about one-third of capacity, at a time when they would typically be at about two-thirds.

As a result, the DWR has allocated only 15 percent of requested amounts of water to be delivered to the SWP in 2009. This allocation is the second lowest in the history of the project. [1-18]… The [Governor's] proclamation further requested that all urban water users immediately increase their water conservation activities in an effort to reduce their individual water use by 20 percent [emphasis added].

3-31
Cont'd

In response to the Governor's proclamation, the California legislature has proposed Assembly Bill (AB) 49 – Water Efficiency[9] and Senate Bill (SB) 261 – Urban Water Efficiency[10]. These proposed bills will require a 10 percent reduction of urban water use by 2015 and 20 percent by 2020. However, these proposed bills will allow the use of non-potable or recycled water to count towards the progress in meeting these targets.

Water districts, in response to the drought, have also taken actions throughout the state such as: 1) asking for voluntary reductions 2) imposing mandatory restrictions or declaring a local emergency 3) imposing agricultural rationing 4) imposing drought rates, surcharges and fines 5) limiting new development and requiring water efficient landscaping and, 6) implementing a conservation campaign. [1-19][emphasis added]

Finally, the District's assertion that reclaimed water use can feasibly and cost-effectively displace an INCREASE in water use requirements in the face of mandated reductions of 20% in potable water can only be substantiated by a thorough analysis --- an analysis that was not conducted. The PEA should acknowledge the cross-media impacts and potential regulatory conflict of the proposed rule. The decision to determine that the impacts are significant does not release the District from analyzing the impacts fully.

Also, the conclusion that potable water impacts could be less than significant with mitigation implies incorrectly that 1) additional recycled water will be available for the specific facilities and 2) the facility has the ability to obtain written declarations from water purveyors that recycled water is not available [see mitigation measures GHG-2 (page 4-31) and HWQ-2 (page 4-84)].

6

In Tables 1-3 and 1-4, Options 1 and 2 of the preferred project show identical emission reductions for different FCCU control technologies. [p. 1-27 and 1-28]

> **Comment 1-6**: We do not understand why the District identified two options for FCCU SOx control with vastly different costs but equal emission reductions. We agree that De-SOx catalyst is less costly than installation of new Wet Gas Scrubbers (WGS); what is unclear is if the level of emission reductions achieved with De-SOx catalyst is equivalent to WGS. The equivalent emission reduction potential should be demonstrated and/or Option 2 analysis should be revised. This analysis should be revised to more clearly define the emission reductions and substantiating documentation. The current analysis is either incomplete or inaccurate.

3-32

Footnote 17 of Table 1-3 indicates the following regarding the potential 0.85 tpd reduction from refinery boilers/heaters: "… the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave." (emphasis added).

> **Comment 1-7**: It is not clear how the proposed RTC shave values were calculated. In addition, because the refinery heaters and boilers are not part of the proposed project, it should be clarified and justified why the "environmental impacts from such controls" are included as part of the project evaluation.
>
> What are the environmental benefits of including refinery heaters and boilers? What emission reductions could they displace? Under RECLAIM, substitution of more cost-effective controls on a site-by-site basis is encouraged, so what benefit is derived from including this specific choice within the Draft PEA?

3-33

EXISTING SETTING (CHAPTER 3)

Table 3-10 (p. 3-67) shows the existing water demand for the facilities that will be affected by the SOx shave.

> **Comment 3-1**: 8 out of 11 facilities have no access to recycled water (see our comments 1-3 and 1-5). In addition, we do not believe that the District's assumption that additional recycled water will be available for those specific facilities from the HRRWPP is correct – thus leading to an incorrect analysis of the impacts to this resource. Yet, the District proposes to offset the increase in use of potable water by expanded use of recycled water.
>
> The analysis should be based on the worst case scenario that none of the facilities specifically will have access to more recycled water, even if the HRRWPP is completed. At the very least, CEQA requires that the District assess the impacts of having to use potable water at those facilities.

3-34

ENVIRONMENTAL IMPACTS (CHAPTER 4)

Table 4-1 (p. 4-2) shows 0.85 tons per day (TPD) emission reduction for Refinery Heaters and Boilers.

> **Comment 4-1**: Refinery heaters and boilers were not included in the proposed rule because no new BARCT is being proposed for this source category. Inclusion of this class of sources within the DPEA is misleading and inappropriate. The CEQA mandates the evaluation of alternatives to the project, not alternatives to technology (i.e., wet gas

3-35

scrubbers) that may be evaluated (but ultimately rejected) as part of the project.

This option comes "out of left field" and there appears to be no documented basis within the context of the proposed rule and DPEA. Inclusion of this "alternative' weakens the DPEA by suggesting alternatives that are not covered by the proposed action.

3-35 Cont'd

Table 4-2 (p. 4-4) summarizes the options for control of the FCCU.

Comment 4-2: The District should document the basis for determining that De-SOx and Wet Gas Scrubbing can produce equivalent emission reductions. Such an analysis, using data from existing facilities (i.e., achieved in practice), is essential if the District is to assess adequately the environmental impacts associated with those technologies.

3-36

Under Option 1, 11 units may be retrofitted with one WGS each at eight facilities by December 31, 2018. Under Option 2, seven units may be retrofitted with one WGS each at five facilities by December 31, 2018. [p. 4-14]

Comment 4-3: It is not clear that these dates match the requirements in the Rule nor that this schedule has any relationship to how companies plan to comply with the final rule requirements. There is no basis for evaluating the potential construction impacts associated with installation of equipment on this schedule.

3-37

Cumulative Air Quality Impacts

"In general, the preceding analysis concluded that air quality impacts from any construction activities would be significant from implementing the proposed project because the SCAQMD's significance thresholds for construction will be exceeded for VOC, NO_x, and PM_{10}. Thus, the air quality impacts due to construction are considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, generate significant adverse cumulative air quality impacts." [4-24]

Comment 4-4: We concur that the proposed regulation (i.e., reduce RTCs by 55%) will cause significant environmental impacts. We believe that the district should consider Alternatives B and C that have much smaller impacts overall. It should be noted that those alternatives would cause significantly fewer environmental impacts (see p. 5-13 through 5-14) – particularly associated with water use and GHG impacts, while still achieving SOx emission reductions called for in the 2007 AQMP (Alternative B) or greater reductions similar to the proposed project (Alternative C).

3-38

Global Climate Change/GHG Impacts

The DPEA lists the following GHG mitigation measures:

"GHG-1 When SOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the SOx control equipment.

GHG-2 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the SOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be supplied to the project." [P. 4-31]

3-39

Comment 4-5: GHG-2 mitigation does not have any mitigating effect on GHG emission. Moreover, it mandates that the source gain a "written declaration" from the water purveyor that is inherently out of the control of the operator. Thus, this condition cannot be imposed on the facility operators (see also ES-4, ES-6, C 1). 3-39 Cont'd

"While there may be additional measures that could eventually be imposed on sources with potential increases in GHG emissions, CARB is adopting measures pursuant to AB 32 that would require the maximum technically feasible and cost-effective GHG emission reductions from most of the industry categories affected by the proposed project. CEQA Guidelines §15364 defines 'feasible' as 'capable of being accomplished in a successful manner within a reasonable period of time…' Specifically, CARB's adopted 'early action measures' include a measure to limit methane emissions from landfills, which SCAQMD staff will enforce." [pp. 4-33 to 4-34]

Comment 4-6: The District's assertion that AB 32 projects will serve as mitigation to the GHG emissions that could be caused by the project makes no sense. Notwithstanding the current uncertainty concerning the ultimate levels of emission reductions, the timing of the reductions, or even how those emission reductions will be achieved, it is unclear how GHG emissions achieved under AB 32 would qualify as mitigation.

The District's approach is incomplete and not helpful in developing approaches that can be used in the subsequent permitting required by projects in order to comply. Issues such as the applicability of BACT, NSR, PSD as well as the effect of EPA's Tailoring Rule (p. 4-33 ff) are unresolved and cannot be resolved before permitting begins.

Hence, projects that are required to comply with the proposed action, and the District as well, would be faced with a Gordian Knot. Again, this issue argues for Alternative B or C that will have many fewer environmental impacts while still resulting in SOx emission reductions called for in the 2007 AQMD (Alternative B) or greater reductions similar to the proposed project (Alternative C). The DPEA is inadequate because it has not identified feasible and reasonable mitigation measures to address GHG impacts. 3-40

"Therefore, GHG BACT is at least as stringent as CEQA's definition of feasible mitigation, which similarly allows consideration of economic, technological and environmental factors. Thus, application of BACT will require the maximum feasible reductions of GHGs at new or modified sources." [p. 4-35]

Comment 4-7: How has the District determined the relationship of GHG BACT to CEQA? No one in USEPA, CARB, or the District has documented the findings, requirements, conditions, emission control efficiencies or technology associated with BACT for GHGs. Even if this is true, it is speculative to assert that BACT for GHGs is as stringent as CEQA mitigation requirements. 3-41

Energy Impacts

"In summary, the energy impacts from both Option 1 and Option 2 of the proposed project are concluded to be less than significant." [p. 4-42]

Comment 4-9: The District did not include in its analysis the additional energy needed to pump potable water (rather than recycled water) to 8 of the 11 facilities that likely will not be able to utilize recycled water to meet the requirements of the rule. This should be included in the PEA. 3-42

Barbara Radlein
October 1, 2010
Page B-7

Hydrology – Water Impacts

"Level of Significance After Mitigation: The analysis shows that proposed increase in total water use under both Option 1 and Option 2 cannot be fully supplied with recycled water (either currently or in the future) and non-potable groundwater and that some potable water may still be required for certain facilities. While the potentially adverse water impacts can be reduced to below significance if facility operators are required to use current and future supplies of recycled water, if available, there is no absolute guarantee at the time of this writing that future supplies of recycled water will be available to the affected facilities included in the HRRWPP Project.

While the use of recycled water can help reduce the water demand impacts substantially, the overall water demand will not be completely mitigated. Therefore, the proposed project will remain significant after mitigation for water demand." [p. 4-84] 3-43

Comment 4-10: Here the District acknowledges that Options 1 and 2 cannot be fully supplied with recycled water. Even if the District Staff concludes the impact will be significant, it does not relieve them of the responsibility to analyze the most likely scenario. The PEA should also analyze the impacts if existing and/or foreseeable water use regulations significantly impede the facilities' use of potable water.

Comment 4-11: As in mitigation measure GHG-2, mitigation measure HWQ-2 mandates that the source gain a "written declaration" from the water purveyor that is inherently out of the control of the operator. Thus, this condition cannot be imposed on the facility operators (see also Comments ES-4, ES-6, C 1). The PEA should identify feasible and reasonable mitigation measures. 3-44

Cumulative Hydrology and Water Quality Impacts: Because the project-specific water demand impacts under Option 1 have been concluded to be significant due to the 500DU potable water demand criteria and in consideration of California's on-going drought and that 100 percent of the potential increase in water use cannot be supplied by recycled water, it could be argued that the proposed project is cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1). Therefore, the proposed project is expected to generate significant adverse cumulative water demand impacts.

However, because the project-specific water quality impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative water quality impacts." [pp. 4-84 to 4-85] 3-45

Comment 4-12: WSPA agrees that with the water demand impacts of the project will be cumulatively significant. Even if the District concludes the impacts will be significant, it does not relieve them of the responsibility to analyze the most likely scenario – no additional supplies of recycled water for the RECLAIM facilities. The PEA should also analyze the impacts if existing and/or foreseeable water use regulations significantly impede the facilities' use of potable water. (See also comment 1-3, 1-5)

"Cumulative Mitigation Measures: The potentially adverse water impacts can be reduced further than initial estimates if recycled water is employed for WGS installations. Even with the use of recycled water as part of the implementing the proposed project, the analysis shows that 100 percent of the proposed increase in total water demand cannot be fully offset by the use of recycled water. While the use of recycled water can help reduce the water demand impacts substantially, the overall total water demand will not be completely mitigated. Therefore, the 3-46

10

proposed project will remain cumulatively significant after mitigation for water demand." [p. 4-85]

Comment 4-13: WSPA agrees with the significance determination but believes the impact analysis should be done assuming no future increases in recycled water. GHG-2 mitigation condition mandates that the source gain a "written declaration" from the water purveyor that is inherently out of the control of the operator.

Thus, this condition cannot be imposed on the facility operators (See also comments 1-3, 1-5, C-1), because its assumption that all the facilities would have access to increased supplies of recycled water is not the likely worst-case scenario as RECLAIM facilities will not have certain access to any new supplies.

3-46 Cont'd

ALTERNATIVES (CHAPTER 5)

Alternatives and BARCT Determination

Please note that Options 1 and 2 of the preferred project are not fully specified in Table 5-1. [p. 5-2]

Comment 5-1: Options 1 and 2 need to be more clearly defined in Table 5-1 because Option 2 is not sufficiently defined to indicate exactly how it (if it in fact can) achieve the same emission reductions. It is not clear how the two Options result in the same emission reductions for different projects and costs. More description of Option 2 and how equivalent emissions reductions can be achieved is needed.

3-47

Footnote 91 of Table 5-1 indicates the following regarding the potential 0.85 tpd reduction from refinery heaters and boilers: "… the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave." (emphasis added)

Comment 5-2: It is not clear how the proposed RTC shave values were calculated. In addition, the refinery heaters and boilers are not even included as part of the proposed project. See Comment 4-1[1].

3-48

In Table 5-2, Options 1 and 2 for Alternative C list SOx emission reductions for Refinery heaters and boilers of 0.85 tpd under "Decreases total operational SOx emissions by 5.48 tpd as follows…"[p. 5-3]

Comment 5-3: The project description for Alternative C on page 5-13 does not include these units as part of the project. Emission reductions associated with these units should not be included as part of the reduction scenario. (See comment 5-2 and 4-1 above)

3-49

[1] *Comment 4-1 Refinery heaters and boilers were not included in the proposed rule because no new BARCT is being proposed. Inclusion of this class of sources within the DPEA is misleading and inappropriate. The CEQA mandates the evaluation of alternatives to the project, not alternatives to technology (i.e., wet gas scrubbers) that may be evaluated (but ultimately rejected) as part of the project. This option comes "out of left field" and there appears to be no documented basis within the context of the proposed rule and DPEA. Inclusion of this "alternative' weakens the DPEA by suggesting alternatives that are not covered by the proposed action.*

Under "Energy Impacts Significant" for the proposed project Option 1 states "the reduction in the use of natural gas is not as much as the proposed project – Option 2" and for proposed project Option 2 states "the reduction in the use of natural gas is more than the proposed project – Option 1". [p. 5-7]

Comment 5-4: These statements are inconsistent with the numbers shown in the Table 2 under "Energy" on page 5-6 which states for both proposed project options "overall reduction in the use of natural gas by 4.1 MMBTU/day." Natural gas reductions for Alternative C (both options) were listed as 34.25 MMBTU/day, eight times greater than the proposed project.

3-50

"…the operation GHG emissions would be less than both Options 1 and 2 of the proposed project. In addition, less than significant adverse secondary impacts for aesthetics, energy, hazards and hazardous materials, hydrology and water quality, and transportation and traffic are expected to result from implementing Alternative C, but these impacts would be less than both Options 1 and 2 of the proposed project." [p. 5-14]

Comment 5-5: Given that less impacts result from implementation of Alternative C while still reducing SOx emissions, it is not clear why Alternative C is not the proposed project, since the SOx reductions are similar (5.48 vs. 6.21 tpd) and the proposed project reductions are far more uncertain.

3-51

"In summary, if Alternative C were implemented, less SO_x reductions would be achieved and less health benefits from reducing SOx overall will be realized." [p. 5-20]

Comment 5-6: An assessment of the difference in health benefits between the proposed project and Alternative C has not been conducted. A linear relationship between increased reductions in SOx and health benefits cannot be assumed for reductions beyond those included in the 2007 AQMP without further multi-pollutant, photochemical modeling analysis. Therefore, to state that there will be additional health benefits from the proposed project versus Alternative C, which provides less significant impacts than the proposed project, is unsubstantiated.

3-52

"However, for Alternative C - Option 2, the adjusted estimate for increased potable water demand would be 108,436 gallons per day, which is below the minimum amount of potable water needed to qualify for as a water demand project per the 500 DU calculations (e.g., 133,911 gallons per day). Thus, for this reason, Option 2 of Alternative C is expected to contribute to less than significant adverse water demand impacts." [p. 5-65]

Comment 5-7: As WSPA stated earlier, we still believe that the District should analyze potable water demand without assuming the facilities will be able to access new and/or greater amounts of potable water.

3-53

"Further, even though Alternative C would require less WGSs to be installed and would require less total water overall, both Option 1 and Option 2 of Alternative C are estimated to have equivalent demands of potable water when compared to Option 1 and Option 2 of the proposed project. With regard to water quality, both Option 1 and Option 2 of Alternative C would generate less wastewater than Option 1 and Option 2 of the proposed project, respectively. Overall, Alternative C has less environmental impacts than the proposed project." (emphasis added) [p. 5-83]

3-54

Comment 5-8: We agree that Alternative C, particularly without inclusion of the unused RTCs, has less environmental impact than the proposed project. We do not believe that the impacts of the District's seizure of "unused" RTCs have been adequately assessed. Aggressive shave reductions will force facilities to alter operations (i.e., over-control) leading to the installation of additional emissions control equipment with attendant costs and environmental impacts.

3-54 Cont'd

"… but it does not achieve the additional SOx reductions and health benefits expected from the proposed project." [p. 5-83 emphasis added]

Comment 5-9: This statement is misleading. Aerosol particulate formation is a highly non-linear process, dependent on a complex location and aerometric conditions. NO additional air quality or health benefits beyond the AQMP have been documented because the analysis has not been done (see Comment 5-6 above). The District should note that even Alternative C, without inclusion of the unused RTCs, results in greater emission reductions than the AQMP.

What the District must do if it wishes to document the need for, and benefit of additional emissions reduction beyond what has been specified in the AQMP, is to conduct an appropriate modeling analysis of the air quality and health impacts associated with more aggressive emission reductions. Without such information, the DPEA is incomplete.

Without the proper analysis, the district's conclusion, that emissions beyond those required by the AQMP can lead to measurable improvements in air quality at the desired monitoring stations is speculative.

3-55

Barbara Radlein
October 1, 2010
Page C-1

ATTACHMENT C: MINOR COMMENTS

WSPA offers the following minor comments on the DPEA, which do not affect the overall assessment of the proposed project or the alternatives, but which are editorial or typographical in nature.

Comment: The air quality and hazardous materials impacts related to sodium hydroxide (NaOH) usage for Alternative B (Table 5-2, p. 5-5, 3rd bullet and p. 5-7) indicate that the impact from increased NaOH usage is "less than the proposed project – Option 1, but equivalent to the proposed project – Option 2" (emphasis added). However, the increase in NaOH usage listed in the table on the previous page (5.45 tpd) is less than the NaOH increases for both options of the proposed project (13.24 tpd and 8.79 tpd for Options 1 and 2, respectively). This apparent inconsistency needs to be corrected. 3-56

Comment: The GHG impacts for Alternative C – Option 1 column (Table 5-2, p. 5-5, 2nd bullet) indicates that the GHG emissions increase is "significant for GHGs, but less than proposed project for both Options 1 and 2." However, although the emissions for Alternative C are less than those for proposed project Option 1, the GHG emissions increase for Alternative C – Option 1 (34,159 MT/yr without mitigation; 33,911 MT/yr with mitigation) is actually greater than proposed project – Option 2 (19,662 MT/yr without mitigation; 19,580 MT/yr with mitigation). Please make this update to Table 5-2, Alternative C - Option 1. 3-57

Comment: The impacts due to traffic for the proposed project (both Options 1 and 2) listed in Table 5.2 (p. 5-9) indicate that the impacts are different under both the construction and operation scenarios; however, the number of construction trips listed in the table (700 trips) is the same for both options of the proposed project, and therefore, this comment is inconsistent with the numbers shown in the table. 3-58

Comment: There also appears to be a typographical error on p. 5-20 of the DPEA, where it references the number of wet gas scrubbers that would be installed under Alternative C – Option 1. The last paragraph on p. 5-20 indicates that this alternative has a total of eight add-on controls, of which six are wet gas scrubbers; however, other references in this chapter of the DPEA indicate that there would be eight wet gas scrubbers installed under this alternative, for a total of ten add-on controls. 3-59

Comment: On the top of page 5-34, the increase in diesel and gasoline is stated as follows: "For Alternative C – Option 1, the analysis shows an overall increase in diesel and gasoline use of approximately 2,410 gallons per day and 1,384 gallons per day, respectively. Similarly for Alternative C – Option 2, the analysis shows an overall increase in diesel and gasoline use of approximately 2,180 gallons per day and 1,384 gallons per day, respectively."

However, the numbers listed in Table 5-25 at the bottom of the same page indicate that the total diesel and gasoline uses for Alternative C – Option 1 are 3,063 gallons per day and 1,354 gallons per day, respectively, and for Alternative C – Option 2 are 2,690 gallons per day and 1,354 gallons per day, respectively. The numbers should be updated as appropriate. 3-60

Comment: For the Alternative C, peak daily water use during construction listed in Table 5-1 appears to be a typo. It should not be the same as the proposed project (52,272 gal/day, p 4-67) but rather 66,000 gal/day (p-5-57). 3-61

Comment: Footnote 12 is missing from Table 1-3. Please add it to the table as it is critical information. 3-62

14

Responses to Comment Letter #3
(Western States Petroleum Association, October 1, 2010)

3-1 SCAQMD staff appreciates the effort made by WSPA in their commitment to follow the January 2010 Work Plan. The collaborative working relationship is also greatly appreciated.

3-2 SCAQMD staff has evaluated the proposals submitted by WSPA regarding the SOx shaves ranging from 25 to 40 percent. However, based on SCAQMD staff's assessment of available control technologies, the WSPA proposals do not appear to qualify as Best Available Retrofit Control Technology (BARCT) in accordance with California Health and Safety (H&S) Code §40440 as well as equivalency to command-and-control regulations, as required under H&S Code § 39616(c)(1). In addition, the SCAQMD's proposal for a 55 percent shave reflects the modifications to the SCAQMD's original proposal of a 67 percent shave made in response to discussions with industry with regard to determining BARCT. SCAQMD seeks the maximum achievable SOx reductions from the proposed project to ensure attainment of the annual PM2.5 standard, since SOx reductions are 15 times more effective than NOx reductions in reducing PM2.5 concentrations. Moreover, future attainment of the 24-hour PM2.5 and revised annual PM2.5 standards will require even greater SOx emissions reductions for attainment. Without sufficient SOx reductions from the proposed project, which is a control measure in the 2007 AQMP, the SCAQMD may have difficulty attaining the revised annual PM2.5 standard. With regard to economic impacts of the proposed project, refer to Response to Comment 3-5. See also the Socioeconomic Impact Report for the proposed project.

3-3 Individual responses to the detailed comments submitted have been prepared and begin with Response to Comment 3-4.

3-4 If the proposed project is adopted, SCAQMD staff has concluded that there would be sufficient SOx RTCs available to maintain trading within the SOx RECLAIM program. This conclusion is based on a 25 percent difference between facility holdings and emissions. In addition, the proposed shave incorporates a 10 percent compliance margin and a safety valve where RTCs are released back to the market in case the RTC price exceeds a $50,000/ton threshold. All of these rule components will assist in maintaining trading within the SOx RECLAIM program.

3-5 The independent consultants, ETS and NEXIDEA, were selected by a four member panel including representatives from the SCAQMD as well as from WSPA. WSPA's member refineries were in agreement with the selected consultants and they were fully paid for by the refineries. The consultants started their project in September 2008. After considerable amount of time spent at the site visits to all six refineries discussing technical issues such as space limitations, utility infrastructure, control technologies, BARCT levels, and time needed for the refineries to install control technologies considering equipment downtime, the consultants finalized their independent studies in April 2009. During this nine-month period working closely with the refineries, the consultants sent their draft analyses to the refineries at least four times for input and comments, and the consultants addressed all the comments received before the reports were finalized. The consultants' team of engineers

carefully listened to all comments and input from the refineries, and incorporated the refineries' input, if technically sound and correct, in their final feasibility and cost analyses.

In March 2010, as part of the Work Plan developed by SCAQMD staff in concert with WSPA representatives, SCAQMD staff hired Norton Engineering Consultants (NEC) to review ETS's and NEXIDEA's analyses. (It should be noted that NEC applied for this project in 2008 together with ETS and NEXIDEA. NEC received the highest score from WSPA in 2008 but was not selected because their bid was higher than the budget allowable in 2008. NEC has also done work for several refineries.) Generally, NEC estimates for capital costs and annual maintenance costs were higher than ETS and NEXIDEA. However, for the FCCU's WGSs, NEC was in close agreement with ETS. Because NEC's estimates for costs were higher than ETS and NEXIDEA, NEC recommended SCAQMD staff to re-estimate the cost-effectiveness values for the project. SCAQMD staff did so and their re-estimated cost-effectiveness values based on NEC's recommendations are presented in Chapter 12, Section 12.2 of the Staff Report. The table below provides a comparison between ETS, NEXIDEA and NEC's estimates:

	ETS/AEC, NEXIDEA	**NEC**
Present Value for 25 Years	$630 million	$738 million
Emission Reductions	4.36 tons per day*	4.21 tons per day*
Cost Effectiveness	15,845 $/ton	19,199 $/ton

*Early reduction was 1 ton per day, applicable to a refinery that installed and operated a WGS for their FCCU since 2008, and a refinery that conducted process modification to their SRU/TGU to reduce emissions pursuant to EPA consent decree. The emission reductions from this FCCU and this SRU/TGU accounted for from 2005 baseline were 1 ton per day. The total emission reductions estimated from 2005 baseline are about (4.36+1=5.36 tons per day) for ETS/NEXIDEA and 5.21 tons per day for NEC.

ETS/AEC and NEC estimated that the actual emission reductions estimated from the 2005 baseline that could be cost-effectively achieved for this project are approximately 5.21 tons per day to 5.36 tons per day. However, to achieve these actual reductions, excess RTCs or "unused" RTCs must be removed to prevent avoidance of installing controls. Thus, SCAQMD staff has estimated that 6.1 tons per day of RTC reductions must be made in order to achieve these actual reductions. The amount of excess or "unused" RTCs estimated for the 2005 baseline was 1.73 tons per day (i.e., the difference between the RTC holdings of 11.77 tons per day and the 2005 audited emissions of 10.04 tons per day) can be counted towards the goal of 6.1 tons per day RTC reductions at no cost to the facilities. In other words, if RECLAIM facilities agree to reduce all "unused" RTCs, the "real" compliance costs to achieve a programmatic 6.1 tons per day RTC reductions could be less than $630 to $738 million estimated by the consultants. WSPA's assessment that the "*The District's overly aggressive proposal incorporates the seizure of "unused" RTC's in a manner that doubles the compliance cost. The costs to achieve emission reductions required by the proposed shave are nearly double the costs required to achieve emission reductions equivalent to installation of BARCT controls on refinery sources*" does not make sense.

With regard to the comment that the Draft PEA should evaluate the costs of achieving BARCT levels, see Response to Comment 1-1.

3-6 The proposed project and Alternative C have identical, significant adverse water demand impacts. With regard to GHG emissions, the analysis for the proposed project indicates the

quantity of GHG emissions would be greater than those analyzed for Alternative C (i.e., by approximately 5,000 MT CO2eq/year), but both the proposed project and Alternative C are shown to have significant adverse impacts for GHG emissions. While there are mitigation measures to help minimize the impacts for water demand and GHGs, the mitigation will not bring the impacts below the applicable significance thresholds (using recycled water can reduce GHG emission impacts up 40 percent in northern California to as much as 81 percent in southern California[23] because less energy is required to collect, treat, and redistribute to the point of use). For these reasons, SCAQMD staff has prepared a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan. This document, referred to as "Attachment 1 to the Resolution," will be included in the Governing Board package.

In addition to Alternative C, SCAQMD staff considered two other alternatives: Alternative A (the "no project" alternative) and Alternative B (the AQMP alternative). While both Alternative A and Alternative B were shown to have less environmental impacts than the proposed project and Alternative C, neither was shown to achieve the goals of the proposed project. Specifically, Alternative A, the 'no project' alternative, does not achieve the goals of the proposed project because it does not implement the AQMP control measure. While no significant adverse secondary environmental impacts would result from the 'no project' alternative, it is not necessarily the environmentally superior alternative in accordance with CEQA Guidelines §15126.6(e)(2) because SOx emissions would continue to be emitted at current levels, thus, not improving air quality in the District.

While less add-on control equipment would be installed overall under Alternative B when compared to the proposed project, the environmental impacts would be less than significant and substantially less than the proposed project but the potential SOx emission reductions would also be less. Because Alternative B is limited to fewer source categories, fewer WGSs would be installed. Of the adverse environmental impacts that would be generated under Alternative B, the impacts would be less than the proposed project and less than significant, except for air quality construction emissions which are identical to the proposed project and are concluded to be significant. Alternative B, with a potential SOx emissions reduction of 1.50 tons per day, only partially achieves the SOx emission reductions identified in the AQMP, which are necessary to demonstrate attainment with state and federal air quality standards. When compared to the proposed project, Alternative B provides fewer benefits to air quality and public health.

Alternative C, with a potential SOx emissions reduction of 5.48 tons per day, achieves slightly less potential SOx emission reductions than the proposed project. When compared to the proposed project, the GHG emissions projected for both options of Alternative C are significant, but less than the proposed project. Because Alternative C employs the same amount of NaOH for Option 1 and Option 2, respectively as the proposed project, it has equivalent toxic impacts when compared to the proposed project. Further, even though Alternative C would require less WGSs to be installed and would require less <u>total</u> water overall, both Option 1 and Option 2 of Alternative C are estimated to have equivalent demands of potable water when compared to Option 1 and Option 2 of the proposed project. Thus, Alternative C has equivalent potable water demand impacts as the proposed

[23] California Air Pollution Control Officers Association (CAPCOA), Quantifying Greenhouse Gas Mitigation Measures, August 2010.

project. With regard to water quality, both Option 1 and Option 2 of Alternative C would generate less wastewater than Option 1 and Option 2 of the proposed project, respectively. Overall, Alternative C has less environmental impacts than the proposed project but it does not achieve the additional SOx reductions and health benefits expected from the proposed project.

3-7 The comment states that if Alternative C was selected in lieu of the proposed project, a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan may not be necessary. The analysis for Alternative C was shown to also have significant adverse impacts for air quality during construction, GHGs, and water demand, even after mitigation measures are employed. Further, the air quality and water demand impacts for Alternative C are identical to the proposed project. For these reasons, if Alternative C was selected, a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan would also be required. However, Alternative C was not selected because even though it has less environmental impacts than the proposed project it does not achieve the additional SOx reductions and corresponding health benefits expected from the proposed project and does not achieve what the SCAQMD staff's analysis concludes to be BARCT.

3-8 WSPA's assessment related to NEC's report, for cement kilns and sulfuric acid plants, which was incorporated into the analysis, is addressed below.

Cement Kilns

NEC review on cement plants on page 7 of NEC's report states, "*The control technology selection [ETS]… for the cement manufacturing plant kiln is not yet commercially proven… NEC expects the cost for wet scrubbing technology to be more cost effective…….*"

On page 10, NEC states, "…*The original estimate did not add any project scope contingency. NEC revised the estimate by adding the required additional ductwork for the new plot location and the project contingency……The original cost (without project scope contingency) was $19.6M and it would rise to $32.7M if project scope contingency equivalent to that used for the FCC scrubbers …is added.*"

SCAQMD staff's estimates of cost effectiveness for cement kilns based on NEC's recommendation are shown in Section 12.2, Chapter 12 of Part 1 of the Staff Report. The following table shows a comparison between the numbers developed based on ETS's and NEC's recommendation:

	ETS	**NEC**
Capital Costs	$19.6 million	$32.7 million
Present Values	$43.7 million	$62 million
Cost Effectiveness	$19,300 per ton	$26,824 per ton

The costs estimated by NEC were higher than those of ETS. However, the control technology selection of ETS, estimated by NEC, was still cost-effective.

SCAQMD staff acknowledges that the control equipment selection made by ETS (i.e., hybrid limestone scrubber) has not yet been installed at a cement manufacturing facility,

however the technology is feasible and cost-effective, and therefore, ETS's recommendation satisfies the BARCT requirements of the H&S Code. Furthermore, NEC recommended wet gas scrubbing as an alternative control technology. NEC indicated that WGS is even more cost-effective than the technology recommended by ETS. Under the RECLAIM program, the cement manufacturing facility is not required to use the technology recommended by ETS, and may select to use WGS, or any other technologies to reduce their emissions so that they can be in compliance with the shave.

Sulfuric Acid Plants

NEC review on sulfuric acid plant on page 7 of NEC's report states, *"The original costs for installation of scrubbers on the sulfuric acid plant .....appear to be underestimated by a factor of 2.5 to 3.*"

Adjusting the costs upward as recommended by NEC, the costs and cost-effectiveness for the sulfuric acid plants were shown in the following table and are compared to NEXIDEA's estimates:

	NEXIDEA	**NEC**
Capital Costs	$ 7 million	$20 million
Present Values	$19 million	$32 million
Cost Effectiveness	$2,016 per ton	$3,431 per ton

Thus, both consultants believe that WGS technology is a feasible method of SOx control for sulfuric acid plants, and cost-effective even using NEC assumptions.

3-9 The Draft PEA concluded that air quality impacts during construction would be significant, while air quality impacts related to the operation of necessary control equipment and related processes would be less than significant. However, the analysis in the Draft PEA showed an increase in criteria pollutants during both construction and operation activities, and these increases can be attributed to construction equipment, worker vehicle trips and on-road truck trips associated with delivery and hauling activities, and not stationary sources. Emissions from construction activities are not subject to offset requirements pursuant to Regulation XIII – New Source Review. Further, the construction worker vehicle trips and operational truck trips do not qualify under the mobile source criteria that would require the emissions to be accumulated and offset pursuant subdivision (g) of Rule 1306 – Emission Calculations. Thus, no offsets would be required for these activities.

When making findings as required by Public Resources Code §21081 and CEQA Guidelines §15091, the lead agency must adopt a reporting or monitoring program for the changes to the project which it has adopted or made a condition of project approval in order to mitigate or avoid significant effects on the environment (Public Resources Code §21081.6 and CEQA Guidelines §15097(a)). To fulfill the requirements of Public Resources Code §21081.6 and CEQA Guidelines §15097, the SCAQMD has developed a mitigation monitoring plan for anticipated impacts resulting from implementing the proposed project. The mitigation measures developed to mitigate the air quality impacts of the proposed project contain standard requirements that have been consistently applied for both SCAQMD rule projects and projects where the SCAQMD is the lead agency. In addition, because of the significant adverse water demand impacts, two additional

mitigation measures were included to require the use of recycled water to mitigate the use of potable water, and the GHGs that may otherwise be generated from utilizing potable water.

Lastly, regarding the applicability of Regulation XVII – Prevention of Significant Deterioration (PSD), based on the quantity of estimated emissions, no component of the proposed project is expected to meet or exceed the annual emissions thresholds outlined in subdivision (s) of Rule 1702 – Definitions. This conclusion is based on the fact that operational criteria pollutant emissions from all affected facilities (Final PEA, Chapter 4, Table 4-7) would be less than the significant increase levels for major sources Rule 1702(s) and shown in the table below. Therefore, PSD would not apply to the proposed project.

	Rule 1702(s) Significant Increase Level	
Pollutant	Tons per Year	Pounds per Day
Carbon Monoxide	100	548
Sulfur Dioxide	40	219
Nitrogen Oxides	100	548
Particulate Matter	25	137
PM10	15	82
Volatile Organic Compounds	40	219

Any permit application submitted by an owner or operator of a facility to install new equipment or modify existing equipment in response to the proposed modifications to the SOx RECLAIM program will be individually evaluated by SCAQMD staff to determine, what, if any, emission increases or decreases would occur, and what applicable SCAQMD rules and regulations would apply as part of the engineering review and permitting process. Permit applications will also be evaluated to determine whether or not the SOx reduction strategies listed in the permits are identified in the PEA for the proposed project and environmental impacts have been analyzed. To the extent that no new control strategies or unique facility characteristics are identified in the permit applications, further environmental analysis would likely not be required. If new SOx control strategies or unique facility characteristics are identified that were not evaluated in the PEA, further environmental analyses may be required. Finally, at the time an application is issued a permit to construct, the mitigation measures outlined in the Mitigation Monitoring Plan would be included as part of the permit conditions. The analysis in the PEA should be able to support permit applications within the scope of the project. Pursuant to current standard practice, SCAQMD staff would evaluate the individual permit applications to determine if any additional CEQA analysis would be required.

3-10 SCAQMD staff has evaluated the proposals by WSPA to increase the amount of the proposed SOx RTC shave, but does not believe that the newly proposed RTC shave would achieve the required BARCT reductions. As a result, SCAQMD staff continues to support the proposed project, which reflects BARCT in accordance with H&S Code §40440 as well as equivalency to command-and-control regulations, as required under H&S Code

§39616(c)(1). Also, the SCAQMD has reduced its initial shave proposal in response to industry concerns regarding costs.

3-11 Under the RECLAIM program, affected facilities have the flexibility to install air pollution control equipment, change method of operations, or purchase RTCs to meet BARCT levels. As such, the Draft PEA analyzes multiple scenarios that illustrate the worst-case effects of applying the various SOx control technologies along with demonstrating the flexibility that is provided by the RECLAIM program to facility operators when it comes to choosing the methods for reducing SOx emissions. Because of the program's built-in flexibility, as a practical matter, there is no way to predict what each facility owner/operator will do. The various alternatives, including the 2007 AQMP analysis (referred to as Alternative B in the Draft PEA), were designed to evaluate the worst-case options available based on the consultants' reports.

3-12 The environmental impacts of the proposed RTC shave are impacts that would occur as a result of facility operators making physical modifications to reduce SOx emissions overall or using unused RTCs (see Response to Comment 3-5). These impacts to air quality (including GHG emissions) and water use, as well as several other environmental topics identified in the NOP/IS, have already been analyzed in the Draft PEA for the proposed project and the alternatives. Further, the socioeconomic effects of the proposed project and the alternatives have also been analyzed and can be found in the socioeconomic report. Moreover, SCAQMD staff has provided a 10 percent margin to help facilities ensure compliance. In addition, the proposed amendments include several safety valves to prevent potential facility shutdowns: 1) gradual annual reductions with extended compliance schedule (from 2012 to 2019); 2) monitoring RTC price trends over a 12-month rolling average; 3) hold public hearing if RTC price exceeds $50,000 per ton (discrete price); and 4) ability for the Governing Board to set aside (give back) up to 100 percent of RTC reductions for any year when RTC price exceeds $50,000 per ton.

ETS/AEC and NEC estimated that the actual emission reductions estimated from the 2005 baseline that could be cost-effectively achieved for this project are approximately 5.21 tons per day – 5.36 tons per day. However, to achieve these actual reductions, excess RTCs or "unused" RTCs must be removed to prevent avoidance of installing controls. Thus, SCAQMD staff has estimated 6.1 tons per day of RTC reductions must be made to achieve these actual reductions. The amount of excess or "unused" RTCs estimated for the 2005 baseline was 1.73 tons per day (i.e., the difference between the RTC holdings of 11.77 tons per day and the 2005 audited emissions of 10.04 tons per day) can be counted towards the goal of 6.1 tons per day RTC reductions at no cost to the facilities. In other words, if RECLAIM facilities agree to reduce all "unused" RTCs, the "real" compliance costs to achieve a programmatic 6.1 tons per day RTC reductions could be less than $630 to $738 million estimated by the consultants.

3-13 SCAQMD staff's estimates of cost-effectiveness based on NEC's recommendations are in Chapter 12, Section 12.2 of the Staff Report, and a comparison of the cost-effectiveness based on NEC/AEC, NEXIDEA and NEC is also Chapter 12, Section 12.3 of the Staff Report. With regard to the comment suggesting that the costs and cost-effectiveness analyses should be included in the Draft PEA, see Response to Comment 1-1.

3-14 The comment states that the need for additional water supplies was not adequately analyzed in the Draft PEA. The total water demand for each source category and each facility for the proposed project and alternatives was quantified and compared to the CEQA significance criteria for water demand. There is a comprehensive analysis of water demand impacts in Chapters 4 and 5 of the PEA and the impacts are summarized in several tables throughout the Draft PEA (e.g., Tables 4-41, 4-42, 4-43, 4-44, 5-38, 5-45, 5-46, 5-47 and 5-48). Detailed calculations supporting the analysis of water demand impacts are included in Appendix B. Further, the quantities and availability of potable water, industrial use water (groundwater) and recycled water that may be needed to implement the proposed project were carefully analyzed facility-by-facility and in cooperation with each facility's water supplier. In addition, water supply data were provided by each of the individual facility operators as a part of a survey and relied upon in the hydrology/water quality analysis in the Draft PEA. A comprehensive analysis of the availability of the various types of water identified here was also prepared in Chapters 4 and 5 of the PEA and the analysis is summarized in several tables throughout the Draft PEA that define the type and amount of water that may be needed to implement the proposed project (e.g., Tables 4-45, 4-46, 4-47, 4-48, 5-39, 5-40, 5-41, 5-49, 5-50, 5-51, and 5-52). The amount of potable water that may be required is within the range of what was considered to be a substantial use of potable water.

The Draft PEA includes a comprehensive evaluation of the use of recycled water as a viable substitute for potable water. Based on input from the various recycled water purveyors, the Draft PEA makes a distinction between the facilities that currently have access to recycled water and those that do not. The Draft PEA also identifies those facilities that currently do not have access to recycled water, but are earmarked to receive future access to recycled water as a result of the anticipated 2013 completion of the Harbor Refineries Recycled Water Pipeline Project (HRRWPP)[24]. Representatives from both the Los Angeles Department of Water and Power (LADWP) and West Basin Municipal Water District (WBMWD) have provided detailed information about the availability of future access to recycled water to specific facilities that may also be affected by the SOx RECLAIM project. Further, these representatives have assured SCAQMD staff that there is an over-abundance of reliable recycled water ready for use. The EIR prepared for the HRRWPP project contains a detailed analysis of the environmental impacts and costs associated with building the pipeline extensions to the existing recycled water infrastructure. Because these impacts are already accounted for in the EIR for the HRRWPP, SCAQMD staff has incorporated by reference the environmental and cost impacts of the Final EIR for the HRRWPP project into the PEA prepared for the proposed project pursuant to CEQA Guidelines §15150. While the PEA for the proposed project incorporates by reference the impacts of building the HRRWPP infrastructure, the PEA includes an analysis of potentially significant adverse impacts from tying in to the HRRWPP infrastructure. Therefore, between the Final EIR for the HRRWPP and the PEA for the proposed project adverse cost and environmental impacts from constructing the HRRWPP and each facility tying in to the HRRWPP have been comprehensively analyzed.

Finally, it should be emphasized here the Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably

[24] Final EIR available online at: http://www.ladwp.com/ladwp/cms/ladwp012729.pdf.

foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Even though the HRRWPP is under construction, it has not yet been fully completed and as such, the affected facilities have not yet tied into the system. For this reason, the PEA does not assume that recycled water will be available and the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For these reasons, potable water demand was found to be significant, so a Statement of Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's consideration.

For further information on the costs associated with the increased water demand, see Response to Comment 1-1. With regard to the comment that the SCAQMD should expand its analysis of water and wastewater use and handling, see also Responses to Comments 3-19, 3-29 and 3-31.

3-15 The comment does not include any information or data indicating that the use of SOx-reducing additives such as De-SOx at rates to meet the proposed BARCT levels would dilute the circulating cracking catalyst and adversely impact gasoline conversion (yield) within the FCCU[25]. The SCAQMD's own analysis also did not find that this would occur.

In 2008, the SCAQMD, WSPA and the refineries worked together and developed a testing protocol for SOx-reducing additives. The protocol was designed to demonstrate the performance and effectiveness of SOx-reducing additives to achieve a level of 10 ppmv or below. Only one out of six refineries elected to participate in the protocol. The participating refinery conducted short-term testing with SOx-reducing catalysts from September 2008 to November 2008. The SOx-reducing catalyst addition was approximately six percent to seven percent of the total catalyst addition, which was approximately 300 to 400 pounds per day. During this short term testing, the FCCU achieved a level of SOx below 10 ppmv without any negative effects on the yield of gasoline conversion. During the testing, in addition to the catalyst addition rate, the refinery carefully monitored numerous operating parameters (e.g., regenerator operating data such as burn mode, temperature, pressure, total air rate, coke burn rate; riser/reactor operating data such as feed preheat and riser temperature, pressure, FCCU feed rate, feed composition, conversion; and many other operating parameters) and no substantial problems with using the SOx-reducing additives were reported. Further, the refinery also conducted a source test for PM10 emissions and demonstrated that the FCCU continually met the requirements of Rule 1105.1, even with the increased use of SOx-reducing additives. Lastly, while the results of this study are confidential and cannot be disclosed in this response, the refinery reported to SCAQMD staff that they did not experience any substantial increase in loading to their SRU/TGU system during the three months of testing.

3-16 SCAQMD staff analyzed the likely SOx control technologies identified by the consultants as well as the refineries to meet BARCT and none suggested a "dry alternative." Dry gas scrubbers operating at 80 percent to 90 percent control efficiency were considered as BARCT for SOx in 1994. However, between 2008 and 2010, two consultants (ETS and NEC) expressed agreement that non-regenerative wet gas scrubbers can achieve from 1

[25] Letter from INTERCAT to SCAQMD, from Guido Aru, Director of Sales of INTERCAT to Dr. Laki Tisopulos, Assistant DEO of SCAQMD, October 10, 2010.

ppmv to 5 ppmv SOx outlet concentration (95 percent control efficiency or more from the 2005 emissions baseline) and thus, should be considered as BARCT. Based upon SCAQMD staff's and the consultants' evaluation of the dry gas scrubber technology, it is unlikely that it would achieve sufficient emission reductions to qualify as BARCT. While these two consultants recommended different types of WGSs, however, they both concurred that WGSs would be cost-effective and SCAQMD staff concurs with the consultants' recommendations. The two consultants both recommended keeping existing ESPs in place for particulate control and placing the wet gas scrubbers downstream of the ESPs. In addition, SCAQMD staff has worked with the refiners to demonstrate the effectiveness of enhanced usage of SOx-reducing additives, a dry technology, as a compliance option.

3-17 While SCAQMD staff acknowledges that the SOx oxidation catalysts have not yet been used at any of the refineries to reduce SOx from SRU/TGUs, the consultants (ETS/AEC) indicated that the catalysts have been used to capture SOx, destroy CO, VOC and PM10 from incinerators, heaters, turbines, and boilers. Therefore, the technology is transferrable to the SRU/TGU application. The consultants provided costs, cost-effectiveness and other parameters such as water usage and energy usage in Module 2. This information was incorporated in SCAQMD's costs and cost-effectiveness analyses for the SOx RECLAIM program and analyzed in the socioeconomic analysis.

In particular, the consultants have identified one facility (Facility A) that may consider employing the use of a proprietary catalytic gas treatment for their SRU/TGU called selective oxidation catalyst marketed by EmeraChem Power LLC as "ESx." The consultants also identified data relative to natural gas, electricity and catalyst consumption and this data was relied upon to determine air, energy and transportation impacts in the Draft PEA. As the ESx process does not utilize water, no water or wastewater impacts were identified. Thus, socioeconomic analysis has already considered costs of this type of control technology. Similarly, in addition to the information above on water and wastewater impacts, the Draft PEA already has analyzed impacts of these technologies on air quality, energy, and solid waste. For a summary of the environmental impacts for the SRU/TGU and ESx at Facility A, refer to Appendix B, Worksheet B-20.

3-18 Both consultants were in agreement that WGS is BARCT for coke calciner and it is cost-effective. NEC concurred with NEXIDEA on the BARCT selection stating, "*NEC concurs with the consultant's recommendation to use a Vendor D scrubber for emission control*."

NEC however thought that the contingency (35 percent) estimated by NEXIDEA was low. NEC suggested a 50 percent contingency instead. In addition, the facility had an issue with the location proposed by NEXIDEA. The facility operators indicated that this location is needed for truck access for coke loading/unloading. NEC reviewed the area and suggested to raise the WGS above the road. For this reason, the costs estimated by NEC were higher than those estimated by NEXIDEA. SCAQMD staff's calculation of cost-effectiveness for the coke calciner are based on NEC's recommendation as shown in Section 12.2, and 12.3 of Chapter 12 of Part 1 of the Staff Report, and is summarized in the following table:

	NEXIDEA	NEC
Capital Costs	$13.3 - $14.8 million	$45.7 million
Present Values	$21 - $23.4 million	$58.8 million
Cost Effectiveness	$9,902 per ton	$23,036 per ton

3-19 The comment states that the Draft PEA should consider a "reasonable, worst-case scenario" which would assume that no additional recycled water would be supplied to the RECLAIM facilities. California Public Resources Code §21159(a)(1) requires an analysis of *reasonably foreseeable* environmental impacts of the methods of compliance [emphasis added]. Further, CEQA Guidelines §15064(d) requires the lead agency to consider direct physical changes in the environment and *reasonably foreseeable* indirect physical changes in the environment which may be caused by the proposed project [emphasis added].

One reasonably foreseeable environmental impact to be expected from the proposed project is that some SOx control equipment such as WGSs could be installed and these devices are water-intensive. However, WGSs do not require the use of potable water in order to function. SCAQMD staff recognizes that the use of water-intensive equipment is a sensitive issue because California is in the midst of a drought. On February 27, 2009, Governor Schwarzenegger proclaimed a state of emergency regarding the drought and the availability and future sustainability of California's water resources. The proclamation directed all state government agencies to utilize their resources, implement a state emergency plan and provide assistance for people, communities and businesses impacted by the drought. The proclamation further requested that all urban water users immediately increase their water conservation activities in an effort to reduce their individual water use by 20 percent and the use of recycled water can be counted towards the progress in meeting this target.

Recognizing that there is a state goal for a 20 percent reduction in potable water consumption on a per capita basis, it is reasonable that any facility that currently has access to recycled water will choose to tie into their existing recycled water pipeline to operate their WGS (or any other water-intensive SOx controls that do not require potable water) instead of only installing a connection to their potable water supply and increasing their use of potable water at the facility. This is especially true because, according to LADWP (see next paragraph), LADWP is providing competitive pricing to its customers to incentivize the use of recycled water. For these reasons, the hydrology analysis in the Draft PEA considers the use of recycled water for those facilities that currently have access to it.

In addition, representatives from both the LADWP and WBMWD have provided detailed information about the availability of future access to recycled water to specific facilities that may also be affected by the SOx RECLAIM project, but do not have access at present. Further, these representatives have assured SCAQMD staff that there is currently an over-abundance of reliable recycled water ready for use. The Draft PEA considers what the potable water demand would be if future recycled water will be available to these facilities. However, the Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. The

conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available.

3-20 Subsequent to the release of the January 2010 Staff Report, manufacturers of SOx-reducing additives such as De-SOx catalyst provided SCAQMD staff with data indicating that 5 ppmv SOx level is achievable for FCCUs. On this basis, BARCT at 5 ppmv may be met by using SOx-reducing additives or WGSs. The potential environmental effects of using SOx-reducing additives in lieu of WGSs for FCCUs have been analyzed in the Draft PEA and have been shown to have less impacts than WGSs. The analysis specific to the use of SOx reducing additives can be found in Appendix B, Worksheet B-31.

3-21 The first set of consultants explored several measures that were specific to fuel gas treatment. Their purpose was to find controls that would lower the fuel gas sulfur that is fed to the refinery boilers and heaters. A 40 ppmv sulfur concentration in the refinery fuel gas has been justified as technologically and economically feasible with SCAQMD Rule 431.1. SCAQMD's proposal does not assume a new BARCT standard for refinery boilers and heaters. In fact, the 40 ppmv fuel sulfur concentration is an existing BARCT standard that was adopted in the May 4, 1990 amendments to SCAQMD Rule 431.1 – Sulfur Content of Gaseous Fuels, and became effective on May 4, 1992; it is still applicable today. However, with the adoption of the RECLAIM program in April 1993, the command-and-control rules, like Rule 431.1, were subsumed, giving the refineries flexibility in complying with this BARCT standard. Over the past 18 years since going into effect, several refineries have avoided meeting the 40 ppmv fuel sulfur concentration BARCT standard under RECLAIM. To the extent that these refineries have avoided meeting that limit because of costs, SCAQMD staff has determined that the proposed shave can be readily met without complying with the 40 ppmv fuel sulfur concentration limit. WSPA's proposal listing various control strategies supports SCAQMD staff's position. As a result, it is not reasonably foreseeable that refiners who avoided complying with the 40 ppmv fuel sulfur concentration limit due to costs would be required to do so now as a result of the proposed shave. Nevertheless, SCAQMD staff has analyzed the potential environmental impacts of complying with the 40 ppmv fuel sulfur concentration limit in the Draft PEA.

3-22 Although not part of SCAQMD's proposal for new BARCT because it is existing BARCT pursuant to Rule 431.1 as explained in Response to Comment 3-21, the consultant ETS/AEC conducted site-specific analyses for fuel gas treatment, and found several possible measures that were cost effective. These are summarized in Module 2 of the consultant's analyses. For this reason, an analysis of the environmental effects associated with fuel gas treatment in the Draft PEA has been included because the consultants' reports indicated that some of the affected facilities may choose to focus on improving SOx emissions from their refinery boilers and heaters in lieu of other equipment. The analysis specific to the refinery boilers and heaters source category identifies the specific facilities that may benefit from SOx reductions. This analysis can be found in Appendix B, Worksheet B-19.

3-23 Nothing in the proposed amended rule would prohibit the use of a "dry" alternative. However, as the commenter pointed out, the CEQA analysis looked at a worst-case scenario of using WGSs, which have a greater water impact. See also Response to Comment 3-16.

3-24 SCAQMD staff would be interested in obtaining more information on the basis for selecting perpetuity credits instead of single-year credits. It should be noted that in a given year, the perpetuity credits would tend to be less expensive than single-year credits because even though the value of perpetuity credits represent an infinite block of emission reductions, on an annualized basis, the value is discounted when compared to a single-year credit. Consequently, the single-year credit would be more a conservative criterion with respect to a RTC trading threshold. Nevertheless, as suggested by the SCAQMD's Executive Officer at the October 14, 2010 Refinery Committee meeting, SCAQMD staff is open to proposals for other trigger thresholds for subparagraphs (f)(1)(M) and (f)(1)(N) in Rule 2002.

3-25 The analysis of the proposed project, which takes into consideration the compliance schedule, demonstrates that the emission reductions as listed in the schedule in the proposed amended rule are achievable while providing a means for giving the affected facilities sufficient time to install the required SOx reducing control equipment. Because facilities will have the flexibility under the RECLAIM program to install air pollution control equipment, change method of operations, and/or purchase RTCs to meet BARCT levels, the analysis in the Draft PEA for the proposed project and each of the alternatives is based on the conservative assumption that multiple projects could be under construction at any one time, regardless of the amount and the year when the RTC reductions would occur. So even if a less aggressive RTC reduction was employed or if more facilities wait until later to implement physical changes to reduce their SOx emissions, the worst-case environmental impacts on a peak daily basis will likely remain unchanged.

3-26 Although the current SOx RTC market may be "thinly traded" as asserted by the commenter, this is not the result of unavailability of SOx RTCs. As noted in Response to Comment 2-26, the surplus SOx RTC pool had approximately 1.73 tons per day of unused RTCs in 2005, and 2.55 tons per day of unused RTCs in 2008. Based on currently available information, SCAQMD staff has concluded that with its proposed shave there should be an adequate supply of RTCs to ensure market stability. The actual availability in the future cannot be substantiated by fact. CEQA recognizes this by stating that a CEQA document "…necessarily involves some degree of forecasting. While foreseeing the unforeseeable is not possible, an agency must use its best efforts to find out and disclose all that it reasonably can." [CEQA Guidelines §15144] Consistent with CEQA, SCAQMD staff has used the best information currently available to project future RTC availability and market responses to project RTC availability (see the Socioeconomic Report for the proposed project). In the event RTC prices spike to a level of concern, a "safety valve," similar to a component in the NOx RECLAIM program, has been added to the SOx RECLAIM program. This "safety valve" sets aside a portion of the RTCs called non-tradable/non-usable RTCs from 2015 to 2019. In a scenario where SOx RTC prices exceed $50,000 per ton, SCAQMD staff will be required to report to the Governing Board at a public hearing. The Governing Board will decide whether to convert any portion of the non-tradable/non-usable RTCs to tradable/usable RTCs, and how much to convert. This approach is expected to help the market regain its balance should the price of RTCs increase above $50,000 per ton because it would increase the RTCs in the market. The "safety valve" provision added to the NOx RECLAIM rules helped stabilize the NOx trading market and there is no reason to believe that it would not have the same effect on the SOx market in the event of price spikes.

3-27 SCAQMD staff recognizes the fact that the design and layout of equipment during construction and installation are key parameters that rely on the appropriate and available plot space. Two sets of consultants were hired specifically to address this issue and made assessments of the available plot space for each control technology measure, so it is incorrect to say that the consultants did "not give adequate weight" to plot space considerations. The consultants based their findings on site visits; their collective experience in refinery technology design, construction, and installation; and on input that was elicited from the affected facilities on several occasions. The consultants' final recommendations identify BARCT that can be installed within the plot space of each individual affected facility based on an analysis of all of the above factors. The consultant reports can be found online at the following URL: http://www.aqmd.gov/rules/proposed.html#RegulationXX.

The commenter notes also, "If the District's assumptions on layout are incorrect, it could mean that a lot more construction must be done which will have greater impacts." First, the comment does not identify which assumptions may be inappropriate. Second, the assumptions with regard to constructing and analyzing impacts from installation of control technologies are clearly laid out in Chapter 4 of the PEA, but the commenter does not provide suggestions for different assumptions. Third, information on construction activities was solicited from affected facility representatives. Finally, the assumptions used in the PEA are considered to be "worst-case" assumptions based on a number of factors including engineering time, time to obtain control equipment and associated materials, availability of appropriately trained construction crews that are able to install the necessary control equipment, etc.

3-28 As discussed in Response to Comment 3-27, the consultants reached their conclusions regarding the availability of plot space and assumptions used in the analysis, the consultants reached their conclusions after visits to the affected facilities and soliciting and receiving input from the affected facility operators. This is why the PEA analyzed different control technologies for each facility. In addition, the comment does not provide any information with regard to why the consultant analysis regarding plot space is inaccurate nor does it provide any recommendations for alternative assumptions or analyses.

3-29 As noted in the PEA, one of the SCAQMD's significance criteria for hydrology/water quality is whether or not the existing water supply has the capacity to meet the increased demands of the proposed project. SCAQMD staff contacted the water purveyors for each of the affected facilities and they have confirmed that that they would be able to supply the needed amount of potable water for the proposed project[26]. In addition, for those facilities that currently have access to recycled water (i.e., Facilities A, B, and D), the applicable water purveyor indicated that it would also be able to supply additional recycled water to accommodate the water demand for the proposed project. Lastly, for those facilities that may have access to future supplies of recycled water (i.e., Facilities C, E, and F), the

[26] Facilities A, B, C, D, E and F: West Basin Municipal Water District, email from Uzi Daniel, February 17, 2010.
Facilities C, E, and F: LADWP, letter from James McDaniel, August 16, 2010.
Facility H: Long Beach Water Department, conversation with Chris Pincherli, August 13, 2010.
Facility I: City of Vernon, email from Scott Rigg, July 28, 2010.
Facility J: No water purveyor; all water is supplied from on-site wells and this facility has unlimited pumping rights.

applicable water purveyor indicated that it would also be able to supply either potable water or recycled water for the proposed project.

The Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Since the HRRWPP has not yet been constructed and the affected facilities have not tied into the system, the PEA does not assume that recycled water will be available. For that reason, the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For these reasons, potable water demand was found to be significant, so a Statement of Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's consideration.

Regarding the infrastructure to increase current supplies of recycled water to Facilities A, B and D as well as to provide future supplies of recycled water to Facilities C, E, and F, representatives from both the LADWP and the WBMWD have assured SCAQMD staff of the following:

1) The existing infrastructure that currently provides recycled water to Facilities A, B and D can handle the proposed increase of additional recycled water to supply the proposed project.
2) The new infrastructure that is currently under construction pursuant to the HRRWPP will provide Facilities C, E, and F with new access to recycled water. The HRRWPP is expected to be completed by Summer 2013. Should any of these facilities install water-based SOx control equipment prior to completion of the HRRWPP, potable water will be supplied. When the HRRWPP is completed, each facility can tie-in to the recycled water pipeline.

The physical and economic feasibility of recycled water pipeline infrastructure has already been evaluated in the Final EIR for the HRRWPP. The HRRWPP would occur regardless of the SCAQMD's proposed project to amend the SOx RECLAIM program. Thus, the Draft PEA need not evaluate the impacts that would occur pursuant to the HRRWPP. See also Response to Comment 3-19.

3-30 From a construction point of view, the installation of a WGS, for example, is a complex process. If a facility operator chooses to install a WGS, the consultants' reports estimate that 18 months would be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and lining up contractors and workers. Further, to physically build a WGS, the consultants' reports indicated that an additional 18 months would be needed. The Draft PEA considers the overlapping construction of building four WGSs within the same 18-month period as a worst-case scenario. This overlap could occur anytime between the date of adoption (scheduled for November 5, 2010) and full implementation (January 1, 2019). However, as a practical matter, even if a facility starts the planning and engineering process immediately if the proposed project is adopted in November 2010 (the currently scheduled public hearing date) to design a WGS installation (and some are in the very early pre-planning stages), construction is not

expected to occur sooner than 2012. For these reasons, the Draft PEA considers any 18-month window between January 1, 2012 and January 1, 2019 (a span of seven years) when facilities could undergo construction activities. Further, based on the practicalities of engineering and constructing applicable control equipment a shorter installation period, such as three years as suggested in the comment, is unrealistic.

3-31 As previously mentioned in Response to Comment 3-19, the Draft PEA analyzes the worst-case potable water demand for the proposed project which was based on data provided by the consultants, the operators of the affected facilities, and the water purveyors. The analysis also takes into account the drought in California, the water conservation measures and the use of recycled water to help meet the water conservation measures. The conclusion of the analysis is that the estimated amounts do not make the proposed project infeasible. As mentioned in Response to Comment 3-29, the water purveyors for each of the affected facilities have confirmed that both potable and recycled water is available and will be supplied to any affected facility that requests it, in amounts necessary to carry out the project.

While it is true that the California legislature has proposed Assembly Bill (AB) 49 – Water Efficiency and Senate Bill (SB) 261 – Urban Water Efficiency, which will require a 10 percent reduction of urban water use by 2015 and 20 percent by 2020, neither of these bills has been adopted by the full legislature. On January 27, 2010, AB 49 was moved to the inactive file[27]. On August 27, 2009, a hearing was set for SB 261 and then canceled[28]. These are the last times any actions were taken on these bills.

In any case, these proposed bills and the water conservation measures share a common concept, which is to allow the use of recycled water to count towards the progress in meeting these targets. Thus, if an affected facility proposes to increase its water use as a result of the proposed project by installing water-based SOx controls, and uses recycled water to satisfy the water demand, the increased use of recycled water would not cause the facility to incur: 1) voluntary reductions; 2) mandatory restrictions during a local emergency; 3) drought rates, surcharges and fines; 4) limits on the new construction subject to water efficient landscaping; or, 5) mandatory conservation. Further, the HRRWPP project is one mechanism designed specifically to convert all of the refineries from potable water to recycled water and the feasibility and cost-effectiveness of this goal was analyzed in the Final EIR for the HRRWPP.

While the preparation of the Draft PEA and in particular, the hydrology analysis, is dependent upon information from the certified Final EIR for the HRRWPP project as it relates to the affected facilities for the SOx RECLAIM project, CEQA Guidelines §15148 requires the document to be cited, but not included in the Draft PEA. Thus, there is no requirement to incorporate or re-analyze in the Draft PEA what was already analyzed and concluded in the Final EIR for the HRRWPP as being cost-effective and feasible with regard to the use of recycled water. The Final EIR for the HRRWPP clearly states and representatives from the LADWP and WBMWD (the project's sponsors) agree that recycled water will be available to the specified facilities (see also Response to Comment 3-29).

[27] http://www.leginfo.ca.gov/pub/09-10/bill/asm/ab_0001-0050/ab_49_bill_20101006_status.html
[28] http://www.leginfo.ca.gov/pub/09-10/bill/sen/sb_0251-0300/sb_261_bill_20090831_status.html

The commenter's statement that the potable water impacts could be less than significant with mitigation is not complete, and is taken out of context. The conclusion states that the overall water demand will not be completely mitigated, even with the use of recycled water. The conclusion can be found on page 4-84 of the Draft PEA. It is important to note that even if mitigation measures cannot fully reduce the impacts to below significance, not being able to fully mitigate the impact would not make the mitigation measure infeasible or unreasonable.

With regard to the remark that the SCAQMD has incorrectly implied that each facility has the ability to obtain written declarations that recycled water is not available pursuant to mitigation measures GHG-2 and HWQ-2, the commenter does not explain why the facilities would not be able to obtain such a declaration. This remark is inconsistent with discussions SCAQMD staff has had with representatives from both the LADWP and WBMWD. Both of these water purveyors have indicated that their staff has met with each facility operator (i.e., those with current supplies of recycled water as well as those with future access to recycled water) as part of a series of on-going negotiations and discussions about their plans to convert from potable water to recycled water. Based on this understanding, there should be no barrier to facility operators obtaining a written declaration from their water purveyor about the status of their current or potential future recycled water supplies. Even if the commenter were correct that the facilities could not obtain such a declaration, this would not change the conclusion that water demand impacts remain significant even after mitigation, but that overriding considerations, nevertheless justify adoption of the proposed project.

It is important to note, however, that the Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Since the HRRWPP has not yet been constructed and the affected facilities have not tied into the system, the PEA does not assume that recycled water will be available. For that reason, the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For these reasons, potable water demand was found to be significant, so Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's approval.

3-32 Two potential control options have been identified for FCCUs: WGSs and SOx-reducing additives. SCAQMD staff believes that 5 ppmv should be the BARCT level for FCCUs based on the performance of an existing WGS installed and operated in the District since 2008. Therefore, the actual emission reductions from the 2005 baseline should be estimated based on a BARCT level of 5 ppmv, and the emission reductions for the two options analyzed in the Draft PEA should both be equal to 2.88 tons per day for FCCUs. SCAQMD staff acknowledges that the 5 ppmv has not yet been fully demonstrated in practice for the SOx-reducing additives. However, short-term testing with a local refinery and multiple discussions with the manufacturers of SOx-reducing additives who have presented SCAQMD staff with actual testing results indicated that the use of SOx-reducing additives can potentially achieve 5 ppmv SOx on a long-term basis. Further, the use of

SOx-reducing additives is not expected to incur any upfront additional capital costs like WGSs. While the annual operating costs are likely to be high for SOx-reducing additives when compared to WGSs, the water demand will be less with SOx-reducing additives. Other environmental impacts and differences between the two technologies are analyzed in the Draft PEA. See also Response to Comment 3-20.

In addition to the fact that both WGSs and SOx-reducing additives may be considered BARCT, the analysis of these technologies also relies on the concept of analyzing maximum impacts that could be created by the technologies to ensure that all potential adverse impacts that may be generated by the proposed project are identified and disclosed to the public. Further, it is important to remember that the PEA is a program level analysis that shows the options a facility may choose to comply with the proposed requirements. The RECLAIM program does not mandate that any particular technology be adopted by facility. For this reason, the analysis is based on those technologies that would allow the facility to comply with the proposed project, while generating the maximum adverse impacts as indicated above.

3-33 The proposed RTC shave values are from Table 13-1 of the Staff Report. They are the RTC reductions in Year 2019 with a 10 percent compliance margin. Although refinery heaters and boilers are not part of the proposed project, they are a potential source of cost-effective SOx reductions. A facility operator may seek additional reductions from this source category if it chooses to. The benefit of analyzing the potential environmental impacts from this source category is that if a facility operator chooses to install controls for refinery heaters and boilers in the future, this PEA may be used for those projects. The SCAQMD encourages the substitution of more cost-effective controls on a site-by-site basis. A facility operator may choose to install cost-effective controls for refinery boilers and heaters and, if those controls achieve further reductions that those specified as Tier 1, then those reductions can be used to displace the reductions from other equipment.

3-34 With regard to the assumptions and analysis associated with the current and future use recycled water as part of implementing the proposed project, see Responses to Comments 3-19, 3-29, and 3-31.

3-35 While it is true that no new BARCT is being proposed for the refinery boilers and heaters source category, the 40 ppm SOx limit was not explicitly included in the previous versions of the SOx RECLAIM rules and as such, is now included in the proposal (see Table 4 in PAR 2002). As explained in Response to Comment 3-22, an analysis of the environmental effects associated with fuel gas treatment in the Draft PEA has been included because the consultants' reports indicated that some of the affected facilities may choose to focus on improving SOx emissions from their refinery boilers and heaters in lieu of other equipment and that choice may have direct and indirect environmental impacts.

3-36 See Responses to Comments 3-20 and 3-32.

3-37 For a discussion about the assumptions associated with timing of construction, see Response to Comment 3-30.

3-38 The analysis in the Draft PEA considers the proposed project and three alternatives. A summary of the environmental impacts can be found in Table 5-60 and shows a side-by-

side comparison of each environmental topic. The comment states that Alternatives B and C "would cause significantly fewer environmental impacts… particularly associated with water use and GHG impacts" than the proposed project. Although the analysis of GHG impacts estimated for Alternative B in Chapter 5 of the PEA are less than significant, the GHG impacts for Alternative C exceed the 10,000 MTCOeq/yr significance threshold.

Similarly for total water demand, neither the proposed project nor any of the alternatives exceed the total water significance threshold. Further, the proposed project and Alternative C have identical, significant potable water demand impacts and only Alternative B has less than significant potable water demand impacts. The comment that there are significantly less impacts from Alternative C compared to the proposed project is inconsistent with analysis of impacts from the project alternatives in Chapter 5 of the PEA. While it is true that Alternative B has less impacts overall when compared to the proposed project, it also achieves the least amount of SOx emission reductions. As a result, the proposed project was preferred over the project alternatives because, even though the proposed project has the potential generate more or more significant adverse environmental impacts, it is more effective at achieving the project objectives than all alternatives evaluated.

3-39 Because there are SOx controls that need water for operation and because the HRRWPP project has identified several facilities that have current or may have future access to recycled water, mitigation measure GHG-2 was designed to work in cooperation with mitigation measure GHG-1 as a backstop to make sure that the water purveyor vouches for the recycled water status at a given facility. In the event that recycled water cannot be delivered to a given facility and potable water needs to be used instead, there will be no reductions in GHG emissions. However, if recycled water is used, there will be less GHGs generated than if potable water was used due to less energy needs for transport. All affected water purveyors have participated in the CEQA process for the proposed project, all have received copies of the PEA and none has expressed concern about this mitigation measure.

3-40 Currently there are two feasible GHG mitigation measures identified in the Draft PEA that are designed to work together to reduce GHG emissions by utilizing recycled water in lieu of potable water, if available. These mitigation measures do not rely on AB 32 projects serving as GHG mitigation measures. AB 32 is mentioned in the Draft PEA as part of the mitigation measure discussion because it is an ongoing process under development by CARB that may result in further GHG emission reductions. While there is nothing in CARB's adopted "early action measures" or CARB's GHG reduction measures that specifically apply to the proposed project as of this writing, CARB has not yet adopted its GHG reduction cap and trade program. When adopted, it is expected to apply to projects that will need to receive permits, including any projects that may occur as a result of amending the SOx RECLAIM program. The purpose of the discussion of AB 32 is to indicate that there are no additional feasible GHG reduction measures that the SCAQMD could adopt that could mitigate impacts from the proposed project, able to go beyond AB 32 requirements.

With regard to applicability of GHG BACT via EPA's Tailoring Rule, the SCAQMD would begin to require GHG BACT for sources already subject to PSD and having a GHG increase of 75,000 MTCO2eq/yr or more, effective January 2, 2011. However, the analysis in the Draft PEA has demonstrated that on an individual facility basis, no facility exceeds

the 10,000 MTCO2eq/yr threshold and for the project as a whole, let alone individual modifications, the GHG emissions do not exceed 75,000 MTCO2eq/yr. Thus, GHG BACT would not apply to the proposed project or any permit action thereafter.

With regard to applicability of NSR and PSD, see Response to Comment 3-9. Lastly, with regard to the comparison of environmental impacts between the proposed project and Alternatives B and C, see Responses to Comments 3-6, 3-7 and 3-38.

3-41 There is a direct relationship between CEQA and GHG BACT as CEQA requires all feasible measures, and GHG BACT is based on what is achievable in practice. Therefore, if GHG BACT can be achieved in practice, then it may also be considered as feasible under CEQA. The purpose of this discussion was to indicate that no additional GHG reduction measures beyond GHG BACT could feasibly be imposed to mitigate impacts from the proposed project.

3-42 The comment states that the Draft PEA did not account for the energy needed to pump potable water to the affected facilities. The analysis in the Draft PEA is based on energy demand from using potable water and does not take any credit for any energy reductions that may occur from using recycled water instead.

3-43 The water purveyors for each affected facility have indicated that, from their perspectives, the proposed increases in water are relatively small. Further, as mentioned in Responses to Comments 3-14, 3-29 and 3-31, the water purveyors have indicated that they can supply the water demand, whether it is for potable water, recycled water or a combination of the two. None of the water purveyor representatives have indicated that there are any regulations in place that would be impediments for them to supply the affected facilities with potable water, if requested, by the facility operators.

3-44 With regard to the appropriateness and feasibility of mitigation measure GHG-2, see Response to Comment 3-39. With regard to the Draft PEA identifying feasible mitigation measures, see Responses to Comments 3-9 and 3-31.

3-45 The comment states that the most likely scenario to analyze would be that there will be no additional supplies of recycled water available to the refineries. This position is not supported by the conclusions in the HRRWPP project and the water purveyor's affirmations, as discussed in Responses to Comments 3-14, 3-29, and 3-31, that both potable water and recycled water will be fully available to the affected facilities. Also, as mentioned in Response to Comment 3-43, none of the water purveyor representatives have indicated that there are any regulations in place that would be impediments for them to supply the affected facilities with potable water, if requested, by the facility operators.

The Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Since the HRRWPP has not yet been constructed and the affected facilities have not tied into the system, the PEA does not assume that recycled water will be available. For that reason, the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For

these reasons, potable water demand was found to be significant, so a Statement of Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's consideration.

3-46 With regard to the Draft PEA analyzing the circumstance of no future increases in recycled water, see Response to Comment 3-19. With regard to the comment that compliance with mitigation measure GHG-2 is out of control of the facility operator and as such it cannot be imposed on a facility, see Response to Comment 3-31.

3-47 While all of the details associated with the proposed project and each of the alternatives are not fully specified in Table 5-1 because it is intended as tool to provide a brief overview or summary, a very detailed description of each component of the proposed project and each alternative is fully described throughout Chapter 5. With regard to how the same emission reductions are expected to be achieved for both options of Alternative C, see Responses to Comments 3-20 and 3-32.

3-48 See Response to Comment 3-33.

3-49 The project description for Alternative C on page 5-13 does not include the refinery boilers/heaters source category because the proposed project does not establish a new BARCT level for refinery boilers/heaters. However, cost-effective emission reductions in the amount of 0.85 ton per day are potentially available from future retrofits in this source category and the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave.

3-50 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that both options of the proposed project are equivalent for natural gas reductions. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Energy Impacts Significant?" row: 1) in the "Proposed Project - Option 1" column: *The reduction in the use of natural gas is equivalent to the proposed project – Option 2*; and, b) in the "Proposed Project - Option 2" column: *The reduction in the use of natural gas is equivalent to the proposed project – Option 1*.

The commenter is correct that the natural gas reductions under both options of Alternative C are approximately eight times greater than the proposed project.

3-51 With regard to why Alternative C is not preferred when compared to the proposed project, see Response to Comment 3-7.

3-52 SCAQMD staff has conducted a sensitivity analysis to assess the future health impacts associated with meeting the PM 2.5 standard in 2020. A health impacts model was run to assess the incremental changes in PM levels as a function of SOx emissions. The analysis showed that reducing PM levels resulted in reductions in premature deaths and chronic bronchitis resulting from reductions in annual average PM2.5 concentrations; and reductions in respiratory and cardiovascular hospital admissions, emergency room visits, asthma symptom days, acute respiratory symptom days, and non-fatal heart attacks. The report on the 2007 AQMP Socioeconomic Analysis can be extrapolated to reflect the health impacts associated with PM as a result of SOx emissions. This was an emissions-based

linear model to estimate the air quality and health impacts in 2020. The studies found that there are health benefits with SOx emission reductions beyond what is specified in the AQMP in the effort to meet the future PM 2.5 standards. Thus, the statement on page 5-20 of the Draft PEA correctly characterizes the potential emission reductions and health benefits of Alternative C relative to those of the proposed project.

3-53 .Regarding analyzing the project without assuming new or increased access to potable water, see Responses to Comments 3-29 and 3-31.

3-54 In order to achieve the air quality benefits reflected by the proposed BARCT standards, it is important that surplus unused RTCs are reduced. The shave methodology used by SCAQMD staff does account for anticipated future growth and provides a compliance range that is within 10 percent of the shave methodologies analyzed prior to RECLAIM amendments. Thus, the shave reductions of the proposed project are designed to meet the 2007 AQMP targets as well as future attainment standards for PM 2.5. The Draft PEA analyzes the potential effects of what facility operators may do to implement the proposed project.

3-55 See Response to Comment 3-52.

3-56 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that the use of NaOH for Alternative B is less than both options of the proposed project. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Air Quality Impacts Significant?" row in the "Alternative B: AQMP" column, third bullet: *Less than significant for TACS use (NaOH) during operations, and less than the proposed project for both Options 1 and 2*.

3-57 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that GHG emissions for Alternative C – Option 1 are less than the proposed project – Option 1 but greater than the proposed project – Option 2. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Air Quality Impacts Significant?" row in the "Alternative C - Option 1" column, second bullet: *Significant for GHGs but less than the proposed project -Option 1 and more greater than the proposed project - Option 2.*

3-58 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that the number of daily truck trips for construction is the same for both options of the proposed project (e.g., 700) and the number of daily truck trips for operation are slightly more for the proposed project – Option 1. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Transportation & Traffic Impacts Significant?" row: 1) in the "Proposed Project - Option 1" column: *Less than significant, but equivalent to the proposed project – Option 2 for construction and more than the proposed project – Option 2 for operation*; and, 2) in the "Proposed Project - Option 2" column: *Less than significant, but equivalent to the proposed project – Option 1 for construction and less than the proposed project – Option 2 for operation.*

3-59 The commenter has identified a typo in the last paragraph on page 5-20. The typo has been corrected to reflect that eight WGSs plus two DGSs for a total of 10 add-on controls were analyzed Alternative C – Option 1.

3-60 The commenter has identified some typos on page 5-34 and Table 5-25. The numbers have been updated and are now consistent with each other.

3-61 The commenter has identified a typo relative to the amount of water needed for construction for both options of Alternative C. The amount of plot space that would be affected by Alternative C is less than the proposed project. This means that the amount of water needed to control the fugitive dust should be about the same or less for Alternative C than the proposed project because the amount of soil that can be disturbed in one day, is physically limited by the amount that construction equipment such as a backhoe can do. For these reasons, the amount of water that may be applied to minimize fugitive dust for Alternative C has been adjusted to be the same as the proposed project during construction (i.e., 52,272 gal/day).

3-62 The commenter has identified a typo relative to Footnote 12 in Table 1-3. The reference has been corrected to reflect Footnote 14 instead.

PREFACE

Since the release of the Draft Socioeconomic Report, a revision has been made to the location of an affected facility. This revision does not affect cost estimates. However, the job impacts have been slightly revised. The total job impacts of the proposed amendments are still within the noise of the economic model used for this assessment.

EXECUTIVE SUMMARY

The proposed amendments to Regulation XX—Regional Clean Air Incentives Market (RECLAIM)—would reduce the allowable SOx emission limits based on current Best Available Retrofit Control Technology (BARCT) for several industrial equipment and processes. A socioeconomic assessment was conducted for the proposed amendments and a summary of the assessment and findings is presented below.

Elements of the Proposed Amendments	The proposed amendments to REgional Clean Air Incentives Market (RECLAIM) would reduce allowable SOx emissions at 11 SOx RECLAIM facilities by reducing their RECLAIM Trading Credits (RTCs). These facilities hold 90 percent of SOx RTCs and generate 95 percent of SOx emissions. In order to ensure that their emissions not exceed the allowable RTCs, these facilities would be required to install or modify SOx emission controls on the following types of equipment and processes: 1) refinery fluid catalytic cracking units (FCCU), 2) refinery sulfur recovery units (SRU), 3) sulfuric acid manufacturing processes, 4) container glass melting furnace, 5) Portland cement manufacturing, and 6) petroleum coke calciner. The proposed amendments would result in a reduction of 4.5 tons and 6.14 tons per day of SOx RTCs in 2014 and 2019, respectively.
Affected Facilities	The proposed amendments will affect 11 SOx RECLAIM facilities. The six affected refineries, one coke calciner unit, and one sulfuric acid plant belong to the sector of petroleum product manufacturing. The refinery FCCU units, refinery sulfur recovery units, refinery boilers/heaters, coke calciner plant, and one sulfuric acid plant operate in this sector. The affected cement and the glass plants belong to the non-metallic mineral product manufacturing sector, and one out of two affected sulfur acid plants belongs to the chemical manufacturing sector. Of these 11 facilities, 10 are located in Los Angeles County and the remaining one is located in San Bernardino County.
Assumptions of Analysis	To meet the proposed SOx reduction, it is expected that the affected facilities would use a variety of SOx control technologies, including wet gas scrubbers (WGSs), dry gas scrubbers (DGSs), EmeraChem ESx catalyst, Cansolv upgrade, and SOx reducing additives. It is further assumed that four WGSs would be installed on the FCCU units at four refineries. It is also assumed that three refineries would install three WGSs and one EmeraChem ESx catalyst on their three affected SRU units. One refinery is expected to install two WGSs on its SRU unit. It is assumed that

Assumptions of Analysis	one of the two affected sulfuric acid manufacturing facilities would use a WGS and the other would use Cansolv upgrade to comply with the proposed amendments. It is assumed that the one affected glass melting facility would install two WGSs, one affected cement plant would install two dry gas scrubbers, and one affected petroleum coke calcining facility would install one WGS scrubber to further control SOx emissions. Control costs vary by equipment type and size. The total compliance cost of the proposed amendments includes one-time cost and recurring costs. The one-time cost includes the capital costs of WGSs, DGSs, EmeraChem ESx catalyst, Cansolv upgrade, and their installations (demolition, concrete, structural, piping, electrical, contractors, contingencies), and major maintenance services at five-year intervals. The one-time costs are annualized assuming a 25-year life for equipment and installation, and a real interest rate of four percent. The annual operating costs include utilities (natural gas, electricity, water, waste water, cooling water, and compressed air), solid waste from catalyst fines, and additional chemicals used. The annual maintenance costs include general maintenance of SOx control equipment, which include both labor and materials, including catalyst replacement.
Compliance Costs	In 2009, ETS Inc. and NEXIDEA Inc. provided cost estimates of SOx emission controls to the District, which was evaluated by Norton Engineering Consultants (NEC) in March 2010. The cost analysis herein is based on the cost estimates provided by these two consultants. The average annual compliance costs are estimated from $32 million to 42 million. Based on the ETS/NEXIDEA estimates, the average annual cost of the proposed amendments is estimated at $32.2 million between 2011 and 2030. The majority of the compliance cost ($28 million or 87 percent) is expected to be incurred by the petroleum product manufacturing sector where the six affected refineries belong. Of the three processes, refinery FCCU units would face the highest annual compliance cost of $17.7 million. The sectors of non-metallic mineral product (affected cement and glass plants) and the chemical manufacturing (one affected sulfur acid plant) are expected to incur lower shares of the total annual compliance cost ($3.14 and $1.03 million, respectively). NEC provided input in calculating capital and maintenance costs estimates for the individual facilities across the six source

	categories and provided cost adjustment factors where applicable. Except for one FCCU in a refinery and a glass plant, NEC's input were higher values than those from the ETS/NEXIDEA. Based on the NEC's cost estimates, the average annual cost of the proposed amendments is estimated at $42 million between 2011 and 2030. The majority of the compliance cost ($36 million or 86 percent) is expected to incur in the sector of petroleum product manufacturing where the six affected refineries belong. Refinery FCCU units would face the highest compliance cost of $18.8 million (43 percent of the total cost).
Employment Impacts	Based on the above assumptions, the compliance cost of proposed amendments provided by ETS/NEXIDEA and inputs from NEC consultants, and the application of the Regional Economic Models, Inc. (REMI) model, it is projected that an average of three to five jobs could be created annually from 2011 and 2030. Equipment installation would start in the year 2011 and through 2019. In earlier years, the positive job impact from the expenditures made by refineries, glass, cement and sulfur acid plants would more than offset the jobs forgone from the additional cost of doing business. The positive job impact would trickle down to the sectors of construction, miscellaneous professional services, retail, wholesale, and business services. However, as refineries, glass, cement, and sulfur acid plants continue to amortize their capital expenditures in earlier years, reductions in job growth would set in, resulting in fewer jobs created in later years. Despite its high compliance costs, the refinery industry is projected to have only four to five jobs forgone annually, on average.
Competitiveness	Affected sectors would experience minor increases in the relative cost of production and relative delivered price with respect to their counterparts in the rest of the U.S. Based on the ETS/NEXIDEA cost estimates, it is projected that the refinery industry would experience a rise in its relative cost of production of 0.18 percent and a rise in its delivered price of 0.12 percent in 2019. Based on the cost estimates derived based on NEC's input, it is projected that the refinery industry would experience a rise in its relative cost of production by 0.21 percent and a rise in its delivered price by 0.15 percent in 2019.
CEQA Alternatives	There are three CEQA alternatives associated with the proposed amendments. Alternative A is the No Project Alternative, which is the existing SOx RECLAIM program. Alternative B is Control Measure CMB-02 (Further SOx Reduction for RECLAIM SOx) in the 2007 AQMP which has lower emission reductions than the proposed amendments. Alternative C would exclude the sulfur

	recovery category from the proposed amendments. There is no Impact from Alternative A. Average annual compliance costs for Alternative B and Alternative C are estimated to be $3.1 and $23.4 million between 2011 and 2030, respectively. Jobs forgone for Alternatives B and Alternative C are estimated to be 29 each between 2011 and 2030, respectively.
WSPA Scenario	Western States Petroleum Association (WSPA) requested that staff analyze a scenario with three times higher costs than staff's estimates for FCCU and sulfur recovery units. The average annual cost of the proposed amendments under this scenario is estimated at $85.2 million between 2011 and 2030. The majority of the compliance cost ($81 million or 95 percent) is expected to be incurred by the petroleum product manufacturing sector where the six refineries belong. Refinery FCCU units would face the highest compliance cost of $53 million (62 percent of total cost). It is projected that an average of 207 jobs could be created annually between 2011 and 2030. In earlier years, the positive job impact from the expenditures made by refineries, glass, cement and sulfur acid plants would more than offset the jobs forgone from the additional cost of doing business. The positive job impact would trickle down to the sectors of construction miscellaneous professional services, retail, wholesale, and business services. It is projected that the refinery industry would experience a rise in its relative cost of production by 0.51 percent and a rise in its delivered price by 0.36 percent in 2019.

INTRODUCTION

The proposed amendments to Regional Clean Air Incentives Market (RECLAIM) would reduce allowable SOx emissions at 11 SOx RECLAIM facilities by reducing their RECLAIM Trading Credits (RTCs). These facilities hold 90 percent of SOx RTCs and generate 95 percent of SOx emissions. In order to ensure that their emissions not exceed the allowable RTCs, these facilities would require to install or modify SOx emission controls on the following types of equipment and processes: 1) refinery fluid catalytic cracking units (FCCU); 2) refinery sulfur recovery units (SRU), 3) sulfuric acid manufacturing processes, 4) container glass melting furnace, 5) Portland cement manufacturing, and 6) petroleum coke calciner. RTCs would be reduced by 4.5 tons and 6.14 tons per day in 2014 and 2019, respectively.

LEGISLATIVE MANDATES

The socioeconomic assessments at the South Coast Air Quality Management District (AQMD) have evolved over time to reflect the benefits and costs of regulations. The legal mandates directly related to the assessment of the proposed rules and amendments include the AQMD Governing Board resolutions and various sections of the California Health & Safety Code (H&SC).

AQMD Governing Board Resolutions

On March 17, 1989 the AQMD Governing Board adopted a resolution that calls for preparing an economic analysis of each proposed rule or amendment for the following elements:

- Affected Industries
- Range of Control Costs
- Cost Effectiveness
- Public Health Benefits

On October 14, 1994, the Board passed a resolution which directed staff to address whether the proposed rules or amendments brought to the Board for adoption are in the order of cost effectiveness as defined in the AQMP. The intent was to bring forth those rules that are cost-effective first.

Health & Safety Code Requirements

The state legislature adopted legislation that reinforces and expands the Governing Board resolutions for socioeconomic assessments. H&SC Sections 40440.8(a) and (b), which became effective on January 1, 1991, require that a socioeconomic analysis be prepared for any proposed rule or rule amendment that *"will significantly affect air quality or emissions limitations."* Specifically, the scope of the analysis should include:

- Type of Affected Industries
- Impact on Employment and the Economy of the Basin

- Range of Probable Costs, Including Those to Industries
- Emission Reduction Potential
- Necessity of Adopting, Amending or Repealing the Rule in Order to Attain State and Federal Ambient Air Quality Standards
- Availability and Cost Effectiveness of Alternatives to the Rule

For the items 1, 4, 5, and 6 above, please refer to Staff Report of Proposed Amended SOx RECLAIM. Additionally, the AQMD is required to actively consider the socioeconomic impacts of regulations and make a good faith effort to minimize adverse socioeconomic impacts. H&SC Section 40728.5, which became effective on January 1, 1992, requires the AQMD to:

- Examine Business and Small Business Impacts; and
- Consider Socioeconomic Impacts in Rule Adoption

H&SC Section 40920.6, which became effective on January 1, 1996, requires that incremental cost effectiveness be performed for a proposed rule or amendment relating to ozone, carbon monoxide (CO), oxides of sulfur (SO_x), oxides of nitrogen (NO_x), and their precursors. Incremental cost effectiveness is defined as the difference in costs divided by the difference in emission reductions between one level of control and the next more stringent control. Incremental cost effectiveness analysis is presented in the staff report prepared for the proposed amendments.

AFFECTED FACILITIES

The proposed amendments will affect 11 SOx RECLAIM facilities that have the following types of equipment or processes: 1) refinery fluid catalytic cracking units (FCCU), 2) refinery sulfur recovery units, 3) sulfuric acid manufacturing processes, 4) container glass melting furnaces, 5) Portland cement manufacturing, and 6) petroleum coke calciner. In addition, the proposed amendments may affect certain existing refinery boilers/heaters that are not meeting the current BARCT limit.

The six affected refineries belong to the sector of petroleum product manufacturing. This sector operates the refinery FCCU units, refinery sulfur recovery units, refinery boilers /heaters, one sulfuric acid plant, and coke calciner units. The affected cement and the glass plants belong to the non-metallic mineral product manufacturing sector, and one out of the two affected sulfur acid plants belong to the chemical manufacturing sector. Of these 11 facilities, 10 are located in Los Angeles County and the remaining one is located in San Bernardino County.

Small Businesses

The AQMD defines a "small business" in Rule 102 as one which employs 10 or fewer persons and which earns less than $500,000 in gross annual receipts. In addition to the AQMD's definition of a small business, the federal Small Business Administration (SBA), the federal Clean Air Act Amendments (CAAA) of 1990, and the California

Department of Health Services (DHS) also provide their own definitions of a small business.

The SBA's definition of a small business uses the criterion of gross annual receipts (ranging from $0.75 million to $35.5 million), number of employees (ranging from 50 to 1,500), megawatt hours generated (4 million), or assets ($175 million), depending on the industry type (US SBA, 2008). The SBA definitions of small businesses vary by 6-digit North American Industrial Classification System (NAICS) code. For instance, the sector of petroleum refineries (NAICS 324110) has 1,500 employees as the threshold below which a business is considered small. For the sector of non-metallic mineral products (NAICS 327310 and NAICS 327213) which includes cement and glass plants, fewer than 750 employees is the criterion below which a business is considered small.

The CAAA classifies a facility as a "small business stationary source" if it: (1) employs 100 or fewer employees, (2) does not emit more than 10 tons per year of either VOC or NOx, and (3) is a small business as defined by SBA.

None of the affected facilities are considered small businesses under any of the small business definitions discussed above. Based on the 2009 annual financial report, the total gross annual revenue of the corporations where the six affected refineries belong (ranging from $16 to $285 billion) was about $945.5 billion. The remaining affected facilities include California Portland Cement Company (CPCC), Rhodia Sulfur Acid Plant, and Owens-Brockway Glass plant. The CCCP is a subsidiary of Taiheiyo Cement Company in Japan with gross annual sales of over $4.3 billion in 2009. The Rhodia and Owens-Brockway companies reported gross annual sales of about $5.2 and $7.1 billion in 2009, respectively.

COMPLIANCE COST

The proposed amendments would require 11 SOx RECLAIM facilities to install or modify SOx emission controls on the following types of equipment and processes: : 1) refinery fluid catalytic cracking units (FCCU), 2) refinery sulfur recovery units, 3) sulfuric acid manufacturing process, 4) container glass melting furnaces, 5) Portland cement manufacturing, and 6) petroleum coke calciner.

In 2009, ETS Inc. and NEXIDEA Inc. provided cost estimates of SOx emission controls to the District, which was evaluated by Norton Engineering Consultants (NEC) in March 2010. The cost analysis herein is based on the cost estimates provided by these two consultants.

Cost Based on ETS/NEXIDEA Estimates

Under the proposed amendments, the SOx RTCs would be reduced to 7.3 tons per day by 2014, and 5.7 tons per day by 2019 from a total of 11.7 tons per day. The affected sources would reduce their emissions to meet the proposed allowable SOx RTCs. Based on the required construction time (Table 1) and cost-effectiveness of control equipment (Table 2), a construction schedule (Table 2) was developed to ensure the projected

emission reductions in 2014 and 2019 would be achieved. It was assumed that the most cost-effective SOx control equipment would be installed or modified first.

Table 1
Construction Time by Source Category and Control Equipment

Source Category	Control Equipment	Required Time
FCCU	Wet Gas Scrubber	3 years
SRU	Wet Gas Scrubber	3 years
Coke Calciner	Wet Gas Scrubber	2 years
Sulfuric Acid	Wet Gas Scrubber	2 years
SRU	Emerachem ESx	2 years
Cement	Dry Gas Scrubbers	2 years
Sulfuric Acid	Cansolv Upgrade	1 year
Glass	Wet Gas Scrubbers	1 year

As shown in Table 2, more expensive controls would not be installed until 2016 to 2019. Based on this schedule and facility-specific estimates, the average annualized cost of the proposed amendments is estimated to be $32.2 million between 2011 to 2030. The refinery FCCU units are estimated to have the highest average annual compliance cost of $17.6 million (55 percent) among all the affected source categories. Table 3 presents the estimated average annual cost of the proposed amendments by equipment

Table 2
Distribution of Control Equipment by Equipment Category and by Cost-Effectiveness (2011-2019)

Equipment Category	2011-12		2013		2014		2015		2016		2017		2018		2019	
	# of Eq	C-E $	# of Eq	C-E $	# of Eq	C-E $	# of Eq	C-E $	# of Eq	C-E $	# of Eq	C-E $	# of Eq	C-E $	# of Eq	C-E $
Refinery FCCU Units					1	12,849	1	14,437			1	36,636			1	42,103
Refinery SRU Units					1	12,880			1	36,359			1	39,000		
Cement Plant[1]			1	19,300												
Glass Plants			1	5,198												
Sulfur Acid Plants	1	1,896	1	5,556												
Coke Calciner			1	9,902												
Total	**1**		**4**		**2**		**1**		**1**		**1**		**1**		**1**	

[1]In late 2009, CPCC announced the shutdown of two cement kilns, which may or may not be permanent, depending on the state of the economy. Table 2 assumes that CPCC would either sell its unused RTCs in 2013 or install control equipment to achieve emission reductions.

Table 3
Average Annual Cost Based on ETS/NEXIDEA Estimates
by Equipment Category
(millions of 2010 dollars)

Equipment Category	2011	2014	2019	2030	Average Annual (2011-2030)
Refinery FCCU Units	$1.93	$11.95	$21.29	$21.29	$17.65
Refinery Sulfur Recovery Units	$0.00	$3.30	$11.30	$11.30	$8.83
Coke Calciner	$0.43	$1.59	$1.59	$1.59	$1.49
Sulfur Acid Plant at Refinery	$0.03	$0.10	$0.10	$0.10	$0.10
Cement Plant	$0.61	$2.81	$2.81	$2.81	$2.62
Glass Plant	$0.00	$0.57	$0.57	$0.57	$0.52
Sulfur Acid Plant	$0.21	$1.11	$1.11	$1.11	$1.03
Total	**$3.21**	**$21.43**	**$38.77**	**$38.77**	**$32.24**

The majority of the compliance cost ($28.07 million or 87 percent) is expected to occur in the petroleum product manufacturing sector where the six affected refineries belong. The refinery FCCU units, refinery sulfur recovery units, coke calciner units, and one of the sulfuric acid plants operate in this sector. The non-metallic mineral product manufacturing sector operates cement and the glass plants. The other affected sulfur acid plant belongs to the chemical manufacturing sector.

Based on the 2009 annual financial report, the total gross annual revenue of the corporations where the six affected refineries belong was about $945.5 billion. Based on this estimate, the refineries total annualized cost ($28 million) represents approximately 0.003 percent of their estimated corporate gross annual sales.

According to the 2009 California State Board of Equalization, the total gasoline sales in California was 14.8 billion gallons, of which the South Coast's share is estimated to be 46 percent. The compliance cost of the proposed amendments, if fully passed on to gasoline consumers, would result in a gasoline price increase of 0.5 cents per gallon in the four-county area.

The detailed compliance cost assumptions for each source category based on consultant's (ETS/NEXIDEA) information on each facility are discussed below.

Refinery FCCUs

The FCCUs are classified as major sources of SOx emissions in RECLAIM, and, as such, the emissions from FCCUs are required to be monitored with continuous emission monitoring system, and reported on a daily basis electronically to the District. There are six refineries that operate six fluid catalytic cracking units (FCCU) in the District. Currently, these refineries are processing low sulfur feed stocks with feed hydro-treating. The proposed amendments would require a BARCT level of 5 ppmv for SOx emissions at these six affected refineries. It is assumed that installation of WGSs could achieve a level of limit of 5 ppmv at these refineries. Out of these six refineries, one has installed a WGS to reduce SOx and PM and is thus already in compliance with the proposed

BARCT limit. As a result, no additional cost was attributed to this facility. Another refinery has heavily treated its FCCU feed to the low 10 ppmv level; therefore, installing a WGS to get to a level of 5 ppmv is not cost-effective. This company may seek additional reductions from other source categories that are affected by the proposed amendments. Therefore, no additional cost was ascribed to this refinery.

The four remaining refineries are assumed to install one WGS each to achieve the proposed SOx emission limit. The total compliance cost of the proposed amendments for refinery FCCUs includes one-time cost and recurring cost. The one-time cost includes the capital cost of WGSs and their installations (demolition, concrete, structural, piping, electrical, contractors, contingencies), and major maintenance services at five-year interval. The analysis herein does not include the equipment salvage values mainly due to the fact that these values will not be realized until after the end of the useful life of the equipment (25 years), which is outside of the model simulation period.[2] The annual costs are additional operating and maintenance costs of those new WGSs.

The capital costs of four new WGSs range from $19.06 million to $39.47 million depending on the characteristics of each refinery. Installation costs of these WGSs range from 27.50 to $51 million. Assuming a 25-year life for equipment and installation, and a real interest rate of four percent, the total one-time annualized cost of compliance for the refinery FCCUs is estimated at $17.06 million. The annualized cost of major maintenance, occurring once every five years, is assumed to be $0.25 million for each refinery.

The annual operating costs include utilities (natural gas, electricity, water, waste water, cooling water, and compressed air), solid waste from catalyst fines, and caustic used. Costs of utilities range from $0.61 to $0.96 million, and the solid waste disposal cost is estimated to be from $0.01 to $0.06 million. The additional caustic usage is estimated at $0.04 to $0.18 million among the four affected refineries. In addition, the total annual maintenance cost at the four refineries is estimated to be $0.62 million. The total recurring cost of compliance for the refinery FCCUs is estimated at $4.24 million.

The total annualized cost of compliance, including capital, operating, and maintenance, is estimated to be $21.3 million.

Refinery Sulfur Recovery Units

Refineries use a sulfur recovery system to maximize sulfur removal from the crude oil. WGSs and EmeraChem Power LLC (selective oxidation catalyst) are assumed as main control strategies to further reduce SO2 emissions from all the sulfur recovery/tail gas treatment (SRU/TG) units at refineries. WGSs are used to control both SOx and particulate emissions and can be installed on sulfur recovery units/tail gas units. EmeraChem ESx catalyst can capture multiple sulfur species, including SO_2, SO_3, and H_2S. In addition to sulfur capture, the catalyst will destroy CO, VOC, and Particulate

[2] The consultants accounted for salvage values of the control equipment and deducted these values upfront from the values of the control equipment.

matter (PM_{10}). It is assumed that two out of the three affected refineries would install three WGSs and the remaining refinery would install an EmeraChem ESx catalyst.

The total compliance cost of the proposed amendments for refinery SRU/TG units includes one-time cost and recurring cost. The one-time cost includes the capital cost of WGSs and EmeraChem ESx catalyst, and their installations (demolition, concrete, structural, piping electrical, contractors, contingencies), and major maintenance services at the five-year interval. The annual costs are additional operating and maintenance costs of those new WGSs and EmeraChem ESx catalyst.

It is assumed that the refineries would install three WGSs and one EmeraChem ESx catalyst on their three affected SRU units. One refinery is expected to install two WGSs. The capital cost of two new WGSs at one refinery is estimated to be $23.2million. The capital cost of one new WGS for the other refinery is estimated to be $14.63 million. The installation cost of those scrubbers is estimated to be $28.10 and 23.18 million, respectively. The capital and installation cost of one EmeraChem ESx catalyst for the third affected refinery is estimated to be $5.14 and $7.53 million, respectively. Assuming a 25-year life for equipment and installation, and a real interest rate of four percent, the total one-time annualized cost of compliance for the refinery SRU units is estimated at $6.66 million. The annualized cost of major maintenance, occurring once every five years, is estimated to be $0.17 to $0.32 million among the affected refineries.

The annual operating costs include utilities (natural gas, electricity, water, waste water, cooling water, and compressed air), solid waste disposal, and soda ash or sorbent used. The cost of utilities is estimated to be $1.36 and $2.84 million for the two new scrubbers, and $0.18 million for the EmeraChem catalyst. The solid waste disposal cost is estimated at $0.03 to $0.05 for the two new scrubbers. The soda ash or sorbent used by these affected refineries is estimated to be $0.02 million. In addition, the total annual maintenance cost of the three refineries is estimated at $0.14 million. The total recurring cost of compliance for the refinery SRUs is estimated at $4.54 million.

The total annualized cost of compliance, including capital, operating, and maintenance is estimated to be $11.20 million.

Sulfuric Acid Plants

Sulfuric acid is a chemical product that is used in manufacturing phosphate and nitrogen fertilizers, detergents, paper, and rust removers. It is also used extensively in automobile manufacturing, metal smelting, water treatment and oil refining processes. There are two facilities in the Basin that manufacture sulfuric acid. It is assumed that one of the two sulfuric acid manufacturing facilities would install a WGS and the other would install a Cansolv upgrade to comply with the proposed amendments.

The total compliance cost of the proposed amendments for sulfuric acid plants includes one-time cost and recurring cost. The one-time cost includes the capital cost of a WGS and capital cost of a Cansolv upgrade, and one-time cost of their installations (demolition, concrete, structural, piping, electrical, contractors, and contingencies). The

annual costs are additional operating and maintenance costs of a new WGS and a Cansolv upgrade.

The capital cost of a new WGS and a Cansolv upgrade is estimated to be $2.4, and $0.35 million, respectively. The installation cost of a new WGS and Cansolv upgrade is estimated to be $3.69 and $0.15 million, respectively. Assuming a 25-year life for equipment and installation, and a real interest rate of four percent, the total one-time annualized cost of compliance for the sulfur acid plants is estimated to be 0.43 million.

The annual operating costs include utilities (electric power, makeup water, makeup caustic, steam usage, waste water treatment), and caustic used. The cost of utilities is estimated to be $0.29 and $0.07 million, for the WGS and Cansolv upgrade, respectively. The caustic usage would cost $0.15 million. In addition, the total annual maintenance cost at the two sulfuric acid plants is estimated to be $0.24 million. The total recurring cost of compliance for the two sulfuric acid plants is estimated at $0.75 million.

The total annualized cost of compliance, including capital, operating, and maintenance is estimated to be $1.18 million.

Glass Plants

SOx emissions from a container glass melting furnace are typically controlled by a dry scrubber followed by a dry electrostatic precipitator (ESP) to control particulates. Two glass melting facilities are in the SOx RECLAIM program, but only one of these facilities is currently operating. It is assumed that the glass melting facility would use two WGSs to further control SOx emissions.

The total compliance cost of the proposed amendments for the one affected glass plant includes one-time cost and recurring cost. The one-time cost includes the capital cost of the two new WGSs and their installations (demolition, concrete, structural, piping, electrical, contractors, contingencies), and major maintenance services at the five-year interval. The annual costs are additional operating and maintenance costs of those new scrubbers.

The capital cost of the two new WGSs is estimated to be $0.93 million. The installation cost of those WGSs is estimated to be $0.96 million. Assuming a 25-year life for equipment and installation, and a real interest rate of four percent, the total one-time annualized cost of compliance for the glass plant is estimated at $0.13 million. The annualized cost of major maintenance, occurring once every five years, is assumed to be $0.01 million.

The annual operating costs include utilities (natural gas, electricity, water, waste water, cooling water, compressed air, solid waste disposal), and caustic used. The cost of utilities is estimated to be $0.18 million, and caustic would cost $0.11 million. The total recurring cost for the one affected glass plant is estimated to be $0.29 million. In addition, the total annual maintenance costs is estimated to be 0.14 million. The total recurring cost of compliance for the affected glass plant is estimated at $0.43 million.

The total annualized cost of compliance, including capital, operating, and maintenance is estimated to be $0.56 million.

Cement Kilns

SOx emissions from cement kilns and coal-fired boilers are generated from combustion of sulfur in the fuel and oxidation of sulfides (e.g., pyrites) in the raw materials when entering the cement kiln. Fuel switching, process alteration, dry and wet scrubbers are commercially available control technologies for reducing SOx emissions. It is assumed that the operator of the cement plant would install two dry gas scrubbers to further control SOx emissions.

The total compliance cost of the proposed amendments for the one affected cement plant includes one-time cost and recurring cost. The one-time cost includes the capital cost of the two DGSs and their installations (demolition, concrete, structural, piping, electrical, contractors, contingencies), and major maintenance services at the five-year interval. The annual costs are additional operating and maintenance costs of those new scrubbers.

The capital cost of the two new DGSs is estimated to be $13.72 million. The installation cost of those DGSs is estimated to be $5.91 million. Assuming a 25-year life for equipment and installation, and a real interest rate of four percent, the total one-time annualized cost of compliance for the cement plant is estimated at $1.72 million. The annualized cost of major maintenance, occurring once every five years, is assumed to be $0.5 million.

The annual operating costs include of utilities (natural gas, electricity, water, waste water, cooling water, compressed air), solid waste disposal, and limestone used. The cost of utilities is estimated to be $1.15 million, and the limestone usage would cost $0.06 million. In addition, the total annual maintenance cost is estimated to be $0.32 million. The total recurring cost of compliance for the affected cement plant is estimated at $1.53 million.

The total annualized cost of compliance, including capital, operating, and maintenance is estimated to be $3.25 million.

Coke Calciners

Petroleum coke, the heaviest portion of crude oil, cannot be recovered in the normal oil refinining process. Instead, it is processed in a delayed coker unit to generate a carbonaceous solid referred to as “green coke.” Green coke with low metals content can be sent to a calciner to make calcined petroleum coke. Calcined petroleum coke can be used to make anodes for the aluminum, steel, and titanium smelting industry.

There is only one petroleum coke calciner in the District and the SOx emissions from the unit are controlled by a dry scrubber. It is assumed that operators of the petroleum coke calcining facility would install a WGS to further control SOx emissions in order to comply with the proposed requirements.

The total compliance cost of the proposed amendments for the one affected coke calciner plant includes one-time cost and recurring cost. The one-time cost includes the capital cost of a WGS and its installations (demolition, concrete, structural, piping, electrical, contractors, and contingencies). The recurring costs are additional operating and maintenance costs of the new scrubber.

The capital cost of a new WGS is estimated to be $5.54 million. The installation cost of a new WGS is estimated to be $7.75 million. Assuming a 25-year life for equipment and installation, and a real interest rate of four percent, the total one-time annualized cost of compliance for the coke calciner plant is estimated at $0.85 million.

The annual operating costs include utilities (natural gas, electricity, water, waste water), and caustic usage. The cost of utilities is estimated to be $0.39 million, and the caustic usage would cost $0.1 million. In addition, the total maintenance cost is estimated to be $0.24 million. The total recurring cost of compliance for the affected coke calciner plant is estimated at $ 0.73 million.

The total annualized cost of compliance, including capital, operating, and maintenance is estimated to be $1.58 million.

Refinery Boilers and Heaters

Some of the existing boilers/heaters at the refineries currently meet the proposed BARCT limit of 40 ppmv, and as such do not need to install additional SOx control equipment. The affected sources in this category may elect to install SOx control equipment as an opportunity to further reduce emissions which are not due to new BARCT. Staff did not develop cost estimates for this category.

Cost Based on Input from NEC

NEC provided capital and maintenance costs estimates for each individual facility across the six source categories. Except for one FCCU in a refinery and a glass plant, NEC's estimates were higher values than those from the ETS/NEXIDEA. Table 4 presents cost adjustment factors by equipment by facility relative to the ETS/NEXIDEA cost estimates.

Table 4
Cost Adjustment Factors
by Equipment Category

Equipment Category	Costs Adjustment Ratio
FCCU (Refinery One)	1.06
FCCU (Refinery Three)	1.21
FCCU (Refinery Four)	1.07
FCCU (Refinery Six)	0.99
SRU (Refinery Two)	1.27
SRU (Refinery Three)	4.29
SRU (Refinery Six)	1.14
Glass (Glass Plant)	1.00
Cement Plant	1.42
Sulfuric Acid Plant (at the Refinery)	1.63
Sulfuric Acid Plant	1.72
Coke Calciner Plant	2.38

Table 5 shows the average annual cost of the proposed amendments by equipment. The total average annual cost of the proposed amendments is estimated at $42 million between 2011 and 2030. The majority of the compliance cost ($36 million or 86 percent) is expected to incur in the sector of petroleum product manufacturing where the six affected refineries belong. Refinery FCCU units would face the highest compliance cost of $18.8 million (43 percent of the total cost).

Table 5
Average Annual Cost Based on NEC's input
by Equipment Category (millions of 2010 dollars)

Equipment Category	2011	2014	2019	2030	Average Annual (2011-2030)
Refinery FCCU Units	$1.92	$12.37	$22.80	$22.80	$18.80
Refinery Sulfur Recovery Units	$0.00	$7.30	$16.94	$16.94	$13.64
Coke Calciner	$1.01	$3.77	$3.77	$3.77	$3.54
Sulfur Acid Plant (at Refinery)	$0.05	$0.17	$0.17	$0.17	$0.16
Cement Plant	$0.87	$4.00	$4.00	$4.00	$3.73
Glass Plant	$0.00	$0.57	$0.57	$0.57	$0.52
Sulfur Acid Plant	$0.36	$1.90	$1.90	$1.90	$1.77
Total	**$4.21**	**$30.08**	**$50.15**	**$50.15**	**$42.16**

EMPLOYMENT AND REGIONAL ECONOMIC IMPACTS

The REMI model (Policy Insight version V.1.1.6) is used to assess the total socioeconomic impacts of a policy change. The model links the economic activities in

the counties of Los Angeles, Orange, Riverside, and San Bernardino. The REMI model for each county is comprised of a five block structure that includes (1) output and demand, (2) labor and capital, (3) population and labor force, (4) wages, prices and costs, and (5) market shares. These five blocks are interrelated. Within each county, producers are made up of 66 private non-farm industries, three government sectors, and a farm sector. Trade flows are captured between sectors and borders as well as across counties and the rest of U.S. Market shares of industries are dependent upon their product prices, access to production inputs, and local infrastructure. The demographic/migration component has 160 ages/gender/race/ethnicity cohorts and captures population changes in births, deaths, and migration.

The assessment herein is performed relative to a baseline without the proposed amendments. Direct effects of the policy change (proposed amendments and CEQA alternatives) have to be estimated and used as inputs to the REMI model in order for the model to assess secondary and induced impacts for all the actors in the four-county economy on an annual basis and across a user-defined horizon (2011-2030). Direct effects of the proposed amendments and CEQA alternatives include additional costs of the proposed requirements to the affected industries and additional goods and services provided by local vendors at the county (or finer) level and by industry. Indirect effects are changes in inter-industry transactions as local suppliers (e.g., construction and miscellaneous professional services) respond to increased demands from directly affected industries (refineries, sulfur acid plans, cement kilns, glass plants). Induced effects reflect changes in local spending that result from personal income changes due to direct and indirect effects.

Refineries, sulfur acid plants, glass plants, and cement plants will face an additional cost of doing business from purchasing new WGSs, DGS, EmeraChem ESx catalyst, and Cansolv upgrade. All the equipment is produced outside of the District and the local economy would thus only benefit from the additional spending on demolition, installation, and operating and maintenance of the new SOx control equipment. The major beneficiaries are the sectors of construction (NAICS 23), miscellaneous professional services (NAICS 54), and utilities (NAICS 22).

Additional costs of doing business to the affected facilities include the annualized capital cost and annual operating and maintenance costs of WGSs, DGSs, EmeraChem ESx catalyst, and Cansolv upgrade. Expenditures on labor are treated as a reduction in labor productivity because more labor will now be required to produce the same amount of output in an industry affected by the proposed amendments.

Employment Impact Based on ETS/NEXIDEA Cost Estimates

The total employment impact of the proposed amendments across industries in key years is shown in Table 6. It is projected that an average of five jobs could be created annually from 2011 to 2030 in the local economy. The minor jobs forgone would fall within the noise of the REMI Model.

Equipment installation to ensure compliance with the proposed amendments is assumed to start in the year 2011 and continue through 2019. In earlier years, the positive job

impact from the expenditures made by refineries, glass, cement and sulfur acid plants would more than offset the jobs forgone from the additional cost of doing business (Table 6). In 2011, 495 additional jobs could be created in the overall economy. The positive job impact would trickle down to the sectors of construction, miscellaneous professional services, retail, wholesale, and business services. However, as refineries, glass, cement, and sulfur acid plants continue to amortize their capital expenditures in earlier years, reductions in job growth would set in, resulting in jobs forgone in later years. Please refer to Appendix A for more details.

The three affected industries where refineries, glass, cement, and sulfur acid plants belong are projected to have one to 11 jobs forgone per year, on average, from 2011 to 2030. Despite having a large share of the total compliance cost, the refinery industry is projected to have fewer jobs forgone relative to other industries with similar magnitude of cost impact due to the fact that the industry is the most capital-intensive. As such, fewer labor would be required to produce the same amount of products or services.

The reduction in disposable income from the overall jobs forgone dampens the demand for goods and services in the local economy, thus resulting in jobs forgone in other sectors such as the rest of manufacturing, retail trade, wholesale, and accommodation and food services.

Table 6
Job Impacts of ETS/NEXIDEA cost Estimates by Industry by Year

Industry	NAICS	Year				Average Annual (2011-2030)

The job impacts include all the companies (affected and unaffected by the proposed amendments) in the respective industries.

Employment Impact Based on NEC Input

The total employment impact of the proposed amendments across industries in key years is shown in Table 7. It is projected that an average of three jobs could be created annually from 2011 to 2030 in the local economy.

Compliance with the proposed amendments is assumed to start in the year 2011 and continue through 2019. In earlier years, the positive job impact from the expenditures

made by refineries, glass, cement and sulfur acid plants would more than offset the jobs forgone from the additional cost of doing business (Table 7). In 2011, 644 additional jobs could be created in the overall economy. The positive job impact would trickle down to the sectors of construction, miscellaneous professional services, retail, wholesale, and business services. However, as refineries, glass, cement, and sulfur acid plants continue to amortize their capital expenditures in earlier years, reductions in job growth would set in, resulting in fewer jobs created in later years.

The three affected industries where refineries, glass, cement, and sulfur acid plants belong are projected to have two to 15 jobs forgone per year from 2011 to 2030. Despite having a large share of the total compliance cost, the refinery industry would have fewer jobs forgone relative to other industries with similar magnitude of cost impact due to the fact that the industry is the most capital-intensive. As such, fewer labor would be required to produce the same amount of products or services.

Table 7
Job Impacts from NEC Input by Industry by Year

Industry	NAICS	Year				Average Annual (2011-2030)
		2011	2014	2019	2030

The job impacts include all the companies (affected and unaffected by the proposed amendments) in the respective industries.

Competitiveness Based on ETS/NEXIDEA Cost Estimates

The additional cost brought on by the proposed amendments would increase the cost of production of the affected industries relative to their national counterparts. Changes in relative production costs would thus be a good indicator of changes in relative competitiveness. The magnitude of the impact depends on the size and diversification of, and infrastructure in a local economy as well as interactions among industries. A large,

diversified, and resourceful economy would absorb the impact with relative ease. Implementation of the proposed amendments would increase the cost of doing business for affected industries.

An index of 0 indicates that there is no change in the cost of production relative to the rest of the United States. An index of above or below 0 means that the cost of production in the four-county areas resulting from the proposed amendments is higher or lower, respectively, than that in the rest of the United States.

Table 8 shows the impact of the proposed amendments on the cost of production by the affected industries and for selected years. The sector of petroleum and coal product manufacturing would experience the largest increase in the relative cost of production (e.g., 0.09 percent in 2014). In 2019, the relative cost of production in this sector would increase to 0.18 percent.

Changes in production costs will affect prices of goods produced locally. The relative delivered price of a good is based on its production cost and the transportation cost of delivering the good to where it is consumed or used. The average price of a good at the place of use reflects prices of the good produced locally and imported elsewhere.

Based on the measurement of relative delivered prices in the REMI model, the proposed amended rule is projected to result in higher delivered prices. These impacts are similar to those on the relative cost of production. For example, the sector of petroleum and coal product manufacturing would experience an increase in relative delivered prices of 0.12 percent in 2019 (Table 8), while other industries will experience minimal increases in relative delivered prices after 2014.

Table 8
Impacts on Relative Cost of Production and Delivered Prices Based on ETS/NEXIDEA Estimates (Relative to the U.S.)

Industry	Relative Cost of Production			Relative Delivered Price		
	2014	2019	2030	2014	2019	2030
Utilities	0.002%	0.002%	0.000%	0.002%	0.001%	0.000%
Construction	0.003%	0.002%	0.001%	0.003%	0.002%	0.001%
Petroleum and Coal Product Manufacturing	0.090%	0.178%	0.166%	0.063%	0.124%	0.114%
Non-Metallic Mineral Product Manufacturing	0.074%	0.068%	0.055%	0.039%	0.036%	0.029%
Chemical Manufacturing	0.006%	0.005%	0.004%	0.004%	0.003%	0.002%

Competitiveness Based on NEC Input

Table 9 shows the impact of the proposed amendments on the cost of production by the affected industries and for selected years. The sector of petroleum and coal product manufacturing would experience the largest increase in the relative cost of production (e.g., 0.11 percent in 2014). In 2019, the relative cost of production in this sector would increase to 0.21 percent.

Based on the measurement of relative delivered prices in the REMI model, the proposed amended rule is projected to result in higher delivered prices. These impacts are similar to those on the relative cost of production. For example, the petroleum and coal product manufacturing sector would experience an increase (0.15 percent) in relative delivered prices in 2019 (Table 9), while other industries will experience minimal increase in relative delivered prices.

Table 9
Impacts of Relative Cost of Production and Delivered Prices Based on NEC's Input (Relative to the U.S.)

Industry	Relative Cost of Production			Relative Delivered Price		
	2014	2019	2030	2014	2019	2030
Utilities	0.003%	0.002%	0.000%	0.003%	0.002%	0.000%
Construction	0.003%	0.002%	0.002%	0.003%	0.002%	0.002%
Petroleum and Coal Product Manufacturing	0.113%	0.214%	0.197%	0.079%	0.149%	0.136%
Non-Metallic Mineral Product Manufacturing	0.100%	0.093%	0.074%	0.052%	0.048%	0.039%
Chemical Manufacturing	0.010%	0.009%	0.007%	0.006%	0.005%	0.004%

CEQA ALTERNATIVES

Staff has identified three alternatives to the proposed amendments, as outlined in the Environmental Assessment prepared pursuant to the California Environmental Quality Act (CEQA). Alternative A, the No Project Alternative, is the existing SOx RECLAIM program. Alternative B is Control Measure CMB-02 (Further SOx Reduction for RECLAIM SOx) in the 2007 AQMP. This alternative seeks SOx emission reductions from the top three most cost-effective controls on equipment/source categories, i.e., sulfuric acid manufacturing, coke calciner, and glass melting furnaces. Alternative C would impose the same SOx limits on fewer equipment/source categories when compared to the proposed project. Specifically, this alternative would exclude the sulfur recovery category.

Table 10 presents a comparison of the alternatives in terms of annual average cost and jobs forgone. Alternative A serves as a benchmark against which other alternatives were evaluated. Of the three remaining alternatives, the proposed project has the highest cost and the lowest jobs impact. Alternative B has the lowest cost ($3.14 million) because fewest source categories would be regulated. This alternative would result in an average of 29 jobs forgone annually. This alternative excludes controls on FCCU and SRU units at refineries and hence would exclude potential jobs that could have been created due to additional expenditure on these controls. Alternative C ($23.40 million) would cost less than the proposed amendments and yet has the same jobs forgone annually as the Alternative B. Both Alternatives B and C would have more jobs forgone than the proposed amendments.

Table 10
Average Annual Impacts of CEQA Alternatives

Alternative	Cost (in millions)	Job Impact
Proposed Amendments*	$32.24	+5
Alternative A	0	0
Alternative B	$3.14	-29
Alternative C	$23.40	-29

*Based on ETS/NEXIDEA Cost Estimates

RULE ADOPTION RELATIVE TO THE COST-EFFECTIVENESS

On October 14, 1994, the Governing Board adopted a resolution that requires staff to address whether rules being proposed for adoption are considered in the order of cost-effectiveness. The 2007 Air Quality Management Plan (AQMP) ranked, in the order of cost-effectiveness, all of the proposed control measures for which costs were quantified. It is generally recommended that the most cost-effective actions be taken first.

The proposed amendments are part of Control Measure CMB-02 (Further SOx Reduction for RECLAIM SOx). It was indicated in the 2007 AQMP that implementation of this control measure would require consideration of facility modernization, as described under Control Measure MCS-01 (Facility Modernization).

Control Measure CMB-02 was ranked 8th with cost-effectiveness from $10,100 to $16,000 per ton of SOx reduced, and Control Measure MSC-01 was ranked 9th with cost-effectiveness of $19,000 per ton of PM2.5 reduced. Cost-effectiveness of the proposed amendments is estimated at $16,000 to $19,000 per ton of SOx (equivalent to $10,700 to $12,700 per ton of PM2.5) reduced and is within the ranking order of cost-effectiveness in the 2007 AQMP.

IMPACTS OF WSPA SCENARIO

Western States Petroleum Association (WSPA) requested an analysis of its scenario, which includes additional costs of compliance in the FCCU and sulfur recovery units (SRU). Based on the WSPA estimates, the compliance costs of WGSs for FCCU and SRU units are three times higher than what the ETS, Inc. and NEXIDEA Inc. had provided to the District staff. The costs of the proposed amendments for other categories of equipment are unchanged.

Cost Impact

Table 11 presents the estimated average annual cost of the proposed amendments by equipment. Under the WSPA scenario, the average annual cost of the proposed amendments is estimated at $85.2 million between 2011 and 2030. The majority of the compliance cost ($81 million or 95 percent) is expected to incur in the sector of

petroleum product manufacturing where the six affected refineries belong. Refinery FCCU units would face the highest compliance cost of $52.9 million (62 percent of the total cost).

Table 11
Average Annual Cost of WSPA Scenario
by Equipment Category (millions of 2010 dollars)

Equipment Category	2011	2014	2019	2030	Average Annual (2011-2030)
Refinery FCCU Units	$5.79	$35.86	$63.89	$63.89	$52.94
Refinery Sulfur Recovery Units	$0.00	$9.92	$33.91	$33.91	$26.49
Coke Calciner	$0.43	$1.59	$1.59	$1.59	$1.49
Sulfur Acid Plant (at Refinery)	$0.03	$0.10	$0.10	$0.10	$0.10
Cement Plant	$0.61	$2.81	$2.81	$2.81	$2.62
Glass Plant	$0.00	$0.57	$0.57	$0.57	$0.52
Sulfur Acid Plant	$0.21	$1.11	$1.11	$1.11	$1.03
Total	**$7.07**	**$51.96**	**$103.98**	**$103.98**	**$85.19**

Employment Impact

The total employment impact of the proposed amendments across industries in key years is shown in Table 12. It is projected that an average of 207 jobs could be created annually from 2011 to 2030 in the local economy.

Compliance with the proposed amendments is assumed to start in the year 2011 and continue through 2019. In earlier years, the positive job impact from the expenditures made by refineries, glass, cement and sulfur acid plants would more than offset the jobs forgone from the additional cost of doing business (Table 12). In 2011, 1,160 additional jobs could be created in the overall economy. The positive job impact would trickle down to the sectors of construction, miscellaneous professional services, retail, wholesale, and business services. However, as refineries, glass, cement, and sulfur acid plants continue to amortize their capital expenditures in earlier years, reductions in job growth would set in, resulting in fewer jobs created in later years.

The three affected industries where refineries, glass, cement, and sulfur acid plants belong are projected to have one to 11 jobs forgone per year from 2011 to 2030. Despite having a large share of the total compliance cost, the refinery industry would have fewer jobs forgone relative to other industries with similar magnitude of cost impact due to the fact that the industry is the most capital-intensive. As such, fewer labor would be required to produce the same amount of products or services.

The reduction in disposable income from the overall jobs forgone dampens the demand for goods and services in the local economy, thus resulting in jobs forgone in other sectors such as the rest of manufacturing, retail trade, wholesale, and accommodation and food services.

Table 12
Job Impacts of WSPA by Industry by Year

Industry	NAICS	Year				Average Annual (2011-2030)

Other Industries		20	18	-24	-11	-5
Government		77	97	-41	-48	2
Total		**1,160**	**1,490**	**-536**	**-355**	**207**

The job impacts include all the companies (affected and unaffected by the proposed amendments) in the respective industries.

Competitiveness Impact

Table 13 shows the impact of the proposed amendments on the cost of production by the affected industries and for selected years. The sector of petroleum and coal product manufacturing would experience the largest increase in the relative cost of production (e.g., 0.25 percent in 2014). In 2019, the relative cost of production in this sector would increase to 0.51 percent.

Based on the measurement of relative delivered prices in the REMI model, the proposed amended rule is projected to result in higher delivered prices. These impacts are similar to those on the relative cost of production. For example, the petroleum and coal product manufacturing sector would experience an increase (0.36 percent) in relative delivered prices in 2019 (Table 13), while other industries will experience minimal increase in relative delivered prices.

Table 13
Impacts of WSPA Relative Cost of Production and Delivered Prices
(Relative to the U.S.)

Industry	Relative Cost of Production			Relative Delivered Price		
	2014	2019	2030	2014	2019	2030
Utilities	0.006%	0.004%	0.000%	0.005%	0.003%	0.000%
Construction	0.004%	0.003%	0.001%	0.005%	0.003%	0.001%
Petroleum and Coal Product Manufacturing	0.251%	0.517%	0.482%	0.175%	0.360%	0.332%
Non-Metallic Mineral Product Manufacturing	0.075%	0.069%	0.055%	0.039%	0.036%	0.029%
Chemical Manufacturing	0.008%	0.006%	0.004%	0.004%	0.003%	0.002%

Subject: Re-submittal of Environ data: April 15

<<SOx RECLAIM April 15 trans note socioecon 09132010.doc>> <<SOx to SCAQMD 04152010A.ppt>>

All: This email and attachments are follow-up to your SOX RECLAIM Working Group meeting and Public Consultation meetings held on September 8. As you will recall, at those meetings, we discussed the need for the District to include, within the Socioeconomic Report, information on compliance costs resulting from the District's original proposal of a 64% reduction in RTCs. During those conversations, it became clear that some of you working on the RECLAIM project may not have been aware of the information we had provided to the District earlier this year. To address this omission, the Environ presentation that we originally submitted to the District on April 15 is again attached for your review and as input to the Socioeconomic Report.

Also, as my note to you suggests, we will soon provide you with additional information on impacts to the petroleum industry and the regional economy. This new information builds upon, and in some cases updates, data included in the April 15 presentation. I hope to schedule a meeting to brief you on this new information in the near future.

Thank you.

Re: Transmittal of Costs to Refinery Operations: Input to Socioeconomic Report and Initial Response to Draft Programmatic Environmental Assessment

Dear Mr. Dabirian and Ms. Radlein,

In our conversations during the SOx Working Group meeting and the Public Consultation Meeting Regarding Proposed Regulation XX – SOx RECLAIM, you requested that we send you the cost data we already provided to the District on April 15.

We are pleased that the District remains interested in understanding the extraordinary costs to the refining industry to comply with the proposed shave, and the potential impacts on the region. However, we are disappointed to see that the data we provided on April 15 was not included in the DPEA. Apparently it also has not been included in the initial socioeconomic analysis. 1-1

To rectify this omission, and to ensure that data from the affected industry is included in the Final Programmatic Environmental Assessment and in the Socioeconomic Report, we have attached the April 15 presentation that was provided to the District.

We are also finalizing our analysis of the possible economic impact of these costs on the petroleum and the region. Upon completion of that work, we will share our findings with you.

If you have any questions, please contact me.

Sincerely,

970 W. 190th Street, Suite 770, Torrance, California 90502

WSPA RECLAIM Cost Estimate

- Objective was to estimate, using confidential company data, costs to comply with 25% and 60% shave in RTC Allocations
- WSPA retained ENVIRON to collect data and perform analysis with the results aggregated and de-identified

1

Survey Methodology

- Companies submitted operating and capital cost estimates to ENVIRON
- Company data included, for example:
  - Modifications to FCCU, SRU/TGU
  - Facility/Process improvements including changes in facility operations that were not associated with FCCU or SRU/TGU such as improved monitoring equipment

2

Survey Methodology (Cont'd)

- Survey Time period: September 2009 – November, 2009.
  - ENVIRON followed up with companies, as appropriate, to verify that the data was submitted on a consistent basis
  - Follow up by ENVIRON and WSPA continues
  - Confidentiality of data continues to be protected

3

Example Cost Calculation

- Costs are Net Present Value of capital and operating costs at 4% for 25 years
  - Tried to emulate method used by the SCAQMD staff.
  - Cost Effectiveness is NPV/emissions reduced over project life.
  - Emissions based on 2005 year

4

Responses to Comment Letter #1
(Western States Petroleum Association, September 13, 2010)

1-1 The commenter has suggested that the PEA should include the submitted cost data as part of the CEQA analysis. However, the comment letter does not raise the potential for any physical changes to the environment which needs to be addressed through CEQA. Under CEQA Guidelines §15131(a), the economic effects of a project shall not be treated as significant effects on the environment. An environmental document may trace a chain of cause and effect from a proposed decision through economic effects to physical changes caused by economic effects. This comment does not contend that the purported economic effects will result in any physical changes. As a result, the focus of the analysis was on the physical changes caused by the proposed project.

CEQA does require public agencies to consider economic and social factors together with technological and environmental factors in deciding whether changes in a project are feasible to reduce or avoid the significant effects on the environment identified in the CEQA document. However, this information need not be presented in the CEQA document itself (CEQA Guidelines §15131(c)). Moreover, the comment does not contend that the project will result in significant adverse environmental impacts.

The SCAQMD presents information related to the economic impacts of the project in the socioeconomic analysis. As such, the Governing Board will be presented with both the PEA and the socioeconomic analysis to consider when reaching a decision on the proposed project.

Subject: FW: Draft Comment Letter PEA Reg XX 09292010(V2)

Bill,
Per our call, attached is another copy of Owens' comment letter on the Reg.XX Reclaim SOx "shave rule".
I understand Ev Ashworth earlier forwarded you a copy of this but his e-mail contained a boilerplate confidentiality provision(as mine probably does below as well) and there was concern at the District whether you could publish the comment letter. This will confirm that you can ignore that confidentiality paragraph on Ev's email(and mine here).
He submitted the letter on behalf of Owens to be published in the public record(as do I).
I also understand Ev messengered hard copies of the Owens letter out to the District for filing as well.
Owens will be setting up a mtg with District to discuss the shave very soon. Thanks fro calling me to clear away any confusion Electronics!
Thanks

Ms. Radlein:

Attached, please find digital copies of the comments provided by the Owens Brockway Vernon California container glass manufacturing facility on the District's Draft Program Environmental Assessment regarding the proposed amendments to Regulation XX-RELCAIM (Rule 2002; the proposed SOx shave). A hard copy, which is addressed to you, will be hand delivered to the front desk later today (probably by mid-afternoon).

If you would, may I ask that you confirm receipt of these digital comments?

Thank you; I would welcome a call should you have questions, etc.

Regards, Ev Ashworth

Re: Proposed Amended Regulation XX –Comments on the Program Environmental Assessment - Owens-Brockway Glass Container Inc. Vernon Facility (SCAQMD ID 7427)

Dear Ms. Radlein:

By this letter, Owens-Brockway Glass Container Inc. Vernon, California facility (Owens Vernon facility) provides its comments on the August 2010 Draft Program Environmental Assessment (DPEA) that the District prepared to consider the impacts of the proposed amendments to Regulation XX, Rule 2002. Specifically, we provide to the District additional technical information that should be considered under the California Environmental Quality Act (CEQA) by the District's decision makers in setting Best Available Retrofit Control Technology (BARCT) for glass manufacturing. As summarized in correspondence previously submitted to the District, the Owens Vernon facility has already installed BARCT, which the District has recognized as Best Available Control Technology for the control of sulfur oxides[1]. Further, there is no example of a glass container manufacturing facility with a control configuration as suggested by the District to represent BARCT. Therefore, it is especially important for the District's CEQA to fully disclose the potential impacts of the proposed BARCT for container glass manufacturing – a technology that has not worked when previously applied by glass manufacturing operations here in Los Angeles

2-1

Background on Owens Vernon Facility

To put these technical issues in perspective, it is helpful to have an understanding of our plant's customers, employees, and our facility's role in sustainable manufacturing resources in the Los Angeles area. The Owens Vernon facility has been in business for over 70 years. Over the past 25 years, some six individual glass container manufacturing facilities have ceased to operate in

2-2

[1] See attached September 22, 2010 comments filed by the Owens Vernon facility with the District.

the Los Angeles basin, such that the Owens Vernon facility is the only remaining container glass manufacturing facility located within the District. We produce between 2 and 3 million glass bottles per day on five production lines pulling from two furnaces and purchase approximately 330 tons/day of recycled glass. We have 260 employees that represent 15 different countries and territories of origin, over one third of whom have worked at the Owens Vernon facility for over 20 years. The average salary for Owens Vernon staff is three times the minimum wage, with medical, dental and pension plan benefits. Our customers are here in Los Angeles; over 75% of our shipments are to customers within 25 miles of the of the Owens Vernon plant. Thus, the Owens Vernon Facility plays a vital role in maintaining sustainable container glass manufacturing in the Los Angeles area.

2-2 Cont'd

It is also important to put our environmental controls into proper perspective. Owens has been an innovator of emission controls on glass manufacturing. At significant cost, our company implemented oxygen-fuel fired glass manufacturing technology to reduce nitrogen oxide (NOx) emissions from high temperature furnace exhaust. This innovative process control technology was installed to comply with NOx RECLAIM allocations. To comply with SOx RECLAIM, Owens Vernon first employed a SOx control system that injected a water-based sorbent into the exhaust stream prior to the existing electrostatic precipitators (ESPs). However, our facility experienced numerous problems with this technology [*Petition for an Ex Parte, Emergency, and a Short Variance*, Case No. 4472-9, Facility ID 007427, May 15, 1997, paragraphs 6-10]. We also note that the Ball-Foster El Monte facility experienced significant operating problems with its wet scrubber technology, which resulted in the company's decision to replace the wet scrubber with a dry scrubber followed by an electrostatic precipitator [*Petition for Modification and Extension of a Variance*, Case No. 108-20, Facility ID 108701, April 9, 1997, paragraphs 6-14].

2-3

Therefore, with the District's approval, Owens Vernon selected dry scrubbing technology (Trona injection) to reduce sulfur dioxide to comply with RECLAIM. It is important to note that this dry scrubbing technology was identified by the District as Best Available Control Technology (BACT) for the control of sulfur oxides. The dry scrubber controls are followed by the existing three ESPs that operate in parallel to remove entrained Trona sorbent and particulate emissions from the exhaust of the two glass melting furnaces. These technologies reduce sulfur oxide emissions by up to 90%. It is critical to note that the Owens Vernon facility actual SOx emission rate (approximately 0.6 pounds/ton of glass pulled) is significantly lower than the permitted SOx emission rate established for the container glass manufacturing facility in Seattle, Washington that is controlled by the wet scrubber technology evaluated by the District in its BARCT determination.

2-4

Summary of Comments on DPEA

With this background, we now turn to consider technical issues that should be properly addressed by the District's DPEA and support the Rule 2002 revisions. In accordance with CEQA, and its Rule 110, the SCAQMD prepared a DPEA to analyze the environmental impacts of the proposed amended Regulation XX (the "Project"). As discussed below, the DPEA fails to comply with CEQA and the CEQA Guidelines (the "Guidelines") for several reasons.

As an overarching premise, an agency implementing a certified regulatory program must adhere to the basic policies and substantive obligations established by CEQA (see Guidelines §15250). Accordingly, an environmental document prepared pursuant to a certified regulatory program must include a description of the project, alternatives to the project, and mitigation measures to minimize any significant adverse environmental impacts (see Pub. Resource Code §21080.5(d)(3)(A)). In addition, public agencies should not approve projects as proposed if there are feasible alternatives or feasible mitigation measures available that would substantially lessen the significant environmental effects of the project (see Pub. Resource Code §21002). And, of course, the agency must support its analysis with substantial evidence. Here, the DPEA failed to meet several of these standards. 2-5

First, the DPEA's analysis of water supply is inadequate. The DPEA does not provide substantial evidence to factually demonstrate that adequate water supplies are available. The DPEA also acknowledges that there are no guarantees for substantial portions of the water supplies that it factored into the supply and demand analysis. In other words, the DPEA is not only relying on speculative water sources, but also relying on unsupported water supply claims. That is impermissible.

In addition, the DPEA's proposed water supply mitigation measures (i.e., HWQ-1 and HQW-2, use of recycle water) are inadequate because the measures do not minimize the water demand impacts of the Project. Also, the DPEA concludes that water demand impacts are significant, but then fails to propose all feasible mitigation measures. Worsening matters, the DPEA's cumulative impact analysis provides no meaningful assessment of the Project's cumulative water demand impacts. These are clear failures of CEQA requirements. 2-6

Second, the DPEA's analysis of greenhouse gas ("GHG") impacts is inadequate. The DPEA concedes that the Project will have a significant GHG impact. As noted above, that triggers the need to propose all feasible mitigation measures. The DPEA, however, only proposes GHG-1 and GHG-2 (i.e., use of recycle water, see p.4-31), which are inadequate from a CEQA perspective. 2-7

Third, the DPEA's analysis of alternatives is inadequate. Without the No Project Alternative, there are only two real alternatives, neither of which have a bearing on container glass 2-8

manufacturing. These two alternatives do not constitute a reasonable range under CEQA, especially considering the Project's wide-reaching effects on the industries subject to Regulation XX. SCAQMD must propose additional alternatives that are capable of reducing the Project's significant impacts.

2-8 Cont'd

Fourth, the DPEA improperly assumes that the Project will allow affected facilities to implement BARCT over a 9-year period, and that the peak construction emissions are expected to occur in 2012. This assumption is not supported with any technical analysis; rather the DPEA simply refers to the proposed compliance dates outlined in Rule 2002 (i.e., 2012-2019). Under CEQA, where specific data are not available, the responsible agency is to make reasonable worst case assumptions. Thus, absent any analysis, the peak construction should be assumed to occur in 2011, as facilities must comply with the SOx shave as of 2012. Further, in response to comments provided by the public, the DPEA assures decision makers that there is adequate production capacity to supply wet scrubber control technology to all affected sources within the seven year compliance period provided by Rule 2002 (See Comment 9, Table 1-1). We have been unable to find technical data in the DPEA to support this assumption. Therefore, consistent with CEQA guidelines, the analysis should be based on reasonable worst case assumptions, which would require that all affected facilities install controls within a two year period, not the seven year period suggested by the DPEA.

2-9

2-10

We provide additional technical data below indicating where impact analyses in the DPEA are deficient in the following areas:

- Aesthetics
- Air Quality
- Air Toxics
- Land Use
- Noise
- Water Demand
- Water Quality

Failure to remedy these deficiencies before approving the Project would be a prejudicial abuse of discretion. Therefore, we respectfully request that the SCAQMD resolve these and other CEQA deficiencies, so that the decision makers are properly informed before taking any action on the Project.

2-11

Aesthetics

In the analysis of Aesthetics impacts from project operation, the DPEA states on p. 4-8 the following:

2-12

- "If any WGS is installed as part of the proposed project ... at any of the affected facilities, the steam plume, though visible, is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant."

- "Further, the visual continuity of the surrounding area is not expected to be adversely impacted because each WGS, if constructed, will be built within the confines of industrial areas and would be visually consistent with the profiles of the existing affected facilities."

The Owens Vernon glass plant is different from some of the other facilities affected by the proposed rule in that there currently are no visible steam plumes at the facility or nearby. Therefore, the addition of a visible plume is not visually consistent with the profile of the existing facility. We also disagree that a scenic highway or corridor within the area of the melting plant is a prerequisite for a significantly adverse affect on aesthetics. It is common practice to address aesthetics impacts for a facility in an industrial area by taking photographs of the facility from various vantage points and superimposing a mockup of the potentially offending visual element (in this case, a steam plume) on each photograph. It is not acceptable to draw broad conclusions regarding an impact that was previously determined to be potentially significant in the NOP/IS without providing the decision makers the means to form their own judgment. We therefore request that the aesthetics section be revised to properly describe the impact of the proposed BARCT on the container glass sector to properly inform the District's decision makers on the visual impacts of the proposed BARCT.

2-12 Cont'd

Air Quality

The DPEA did not address what the effect would be on the impact of NOx emissions from the furnaces due to installation of wet gas scrubbers. The exhaust streams from the furnaces currently pass through dry gas scrubbers and electrostatic precipitators (DGS-ESP). Further treating by wet scrubbers would result in evaporative cooling of the exhaust. The cooler resulting plumes would have substantially less buoyancy and plume rise, and the ground-level concentrations of pollutants not affected by the WGS (such as NOx) would be higher. To get a sense of this effect, the EPA SCREEN3 dispersion model was used to quantify the potential increase in maximum one-hour average NOx concentration. The assumed stack parameters with and without the WGS cooling effect are shown in the table below:

2-13

Parameter	Without WGS*	With WGS
Exhaust Temperature (°F)	650	150

Parameter	Without WGS*	With WGS
Flow Rate (acfm)	30,000	30,000
Stack Height (ft)	80	80
Stack Diameter (ft)	3.5	3.5
Building Height (ft)	40	40
Building Length (ft)	150	150
Building Height (ft)	100	100

*DGS-ESP case

The only difference in the modeled parameters is the exhaust temperature. The exhaust temperature for the DGS-ESP case was approximated from source test data. The temperature for the WGS case was approximated from manufacturer's data. The stack height and diameter are the values for the current ESP stacks at the Owens Vernon facility. The building dimensions, however, are a very simplified representation.

In both cases, the SCREEN3 model was run with a NOx emission rate of 2.0 g/s, which equates to 380 lb/day, the approximate average daily NOx emission rate for the Owens Vernon facility.

2-13
Cont'd

The SCREEN3 results, which are shown in the attached output files, indicate that there is the potential for a substantial difference in predicted maximum one-hour average ground level concentration. The DGS-ESP case yielded a maximum NOx concentration of 30 $\mu g/m^3$ at 120 meters downwind, whereas the WGS case yielded a maximum NOx concentration of 50 $\mu g/m^3$ at 187 meters downwind.

These results are interpreted as follows. The federal one-hour average NO_2 standard established in April of this year by the EPA is 189 $\mu g/m^3$. The background NO_2 concentration (i.e., design value) for the Vernon area, as represented by the central LA monitor, is 158 $\mu g/m^3$. If 75% of the modeled NOx is assumed to be in the form of NO_2, a common assumption for screening level modeling, then the total NO_2 impact (background plus stack impact) is 180 $\mu g/m^3$ for the DGS-ESP case. For the WGS case, however, the total concentration is 195 $\mu g/m^3$. Therefore, this simple screening analysis demonstrates that the cooler exhaust that would result from adding WGS technology has the potential to create an exceedance of the federal one-hour average NO_2 standard. Therefore, the DPEA should have evaluated this potentially significant air quality impact. We note that the DPEA does not even recognize this new standard as an applicable requirement. At a minimum, the District should evaluate the extent

to which the Rule 2002 amendments will cause or contribute to an exceedance of the new federal one hour nitrogen dioxide standard.

2-13 Cont'd

As discussed above, the DPEA concedes that the Project will have a significant GHG impact. As noted above, that triggers the need to propose all feasible mitigation measures. The DPEA, however, only proposes GHG-1 and GHG-2 (i.e., use of recycle water, see p. 4-31), which are inadequate from a CEQA perspective. At a minimum, the District should follow the outline of proposed GHG mitigation measures in the recently released California Air Pollution Control Officers Association's *Quantifying Greenhouse Gas Mitigation Measures* (see http://www.capcoa.org/). Absent this GHG mitigation analysis, a decision maker cannot reasonably conclude that all feasible GHG mitigation measures have been applied.

2-14

Air Toxics

The DPEA should not limit the evaluation of sodium hydroxide (NaOH) operational impacts to the calculation of emissions from storage tank filling and working losses (as identified in Tables 4-8 and 4-9). The potential for NaOH emissions from the proposed wet gas scrubber should also be considered. Any time a chemical solution is sprayed into a chamber through which a gaseous stream passes; there is the potential for the resulting small droplets to be carried along with the stream as drift or mist. Therefore, worse-case emission calculations should consider NaOH slip out the WGS stack into the ambient air. We realize that mist eliminators could be installed in the WGS units to reduce these emissions, but the uncontrolled emission rate(s) should be calculated and compared to the most stringent Rule 1401 Screening Emission Level for NaOH (i.e., 0.004 pounds per hour). The cost of these controls, if necessary, should be factored into the cost effectiveness analysis. Further, the impact of the pressure drop introduced by this supplemental control system on the integrity of the overall process, including the glass furnaces, dry scrubber, and ESP controls must be considered.

2-15

Land Use

The District's technical analysis does not consider what will happen should the Owens Vernon facility be unable to afford new, yet-to-be demonstrated control configurations, or secure adjusted RECLAIM Trading Credits in sufficient quantities to continue to operate. Should the Owens Vernon facility be forced to discontinue operations, over 100,000 tons/year of recycled glass will either have to be landfilled, or shipped out of the basin. Over two to three million glass containers per day will have to be shipped into the basin to our customers. Therefore, the DPEA should be revised to consider the following impacts:

2-16

- Loss of tax revenue from closure of the Vernon facility

- Loss of employment to 260 workers
- Loss of recycle capacity, and impact on neighboring landfills or from shipment of recycle glass to other locations
- Loss of container glass capacity, and the air emissions/impacts associated with shipment of container glass into Los Angeles via ship, truck and rail

These are reasonably anticipated to occur, given that the Vernon facility is now the last remaining container glass plant in Southern California.

2-16 Cont'd

Noise

The DPEA acknowledges that SOx control equipment proposed by BARCT may add new sources of noise at affected facilities, but the DPEA concludes without substantive analysis that this additional noise is not expected to be noticeable at the property line and will be within allowable noise levels set by OSHA and local noise ordinances. Notably, the DPEA provides no quantification to support this conclusion. Significantly, this conclusion is not consistent with the Ball Foster wet scrubber retrofit project, which resulted in a significant increase in noise complaints from residents and other businesses around their El Monte facility. To address these public complaints, Ball Foster installed, at considerable expense, noise attenuators and other technology to lessen the noise impact of the wet scrubber controls. As discussed elsewhere in our comments, technical problems associated with the wet scrubber technology could not be overcome, such that the wet scrubber was removed, and replaced with dry scrubber/ESP controls. The DPEA should be revised to properly summarize the direct experience at Ball Foster, quantify the incremental acoustic impact of wet scrubber technology on all affected units, and provide mitigation, as necessary, to comply with OSHA and local noise ordinances.

2-17

Water Demand

The DPEA concedes that the Project demands 52,272 gallons per day ("gpd") for construction activities and up to 883,368gpd for operation. DPEA, pp. 4-67, 4-83. To meet this significant demand, the DPEA states that SCAQMD staff has been coordinating with various water suppliers who claim that there will be sufficient water supplies for the Project. The DPEA, however, does not provide substantial evidence to support that assertion or factually demonstrate that adequate water supplies are available. The DPEA also acknowledges that there are no guarantees for substantial portions of the water supplies that it factored into the supply and demand analysis. In other words, the DPEA is not only relying on speculative water sources, but also relying on unsupported water supply claims. That is impermissible.

2-18

In addition, the DPEA's proposed water supply mitigation measures (i.e., HWQ-1 and HQW-2) are inadequate because the measures do not minimize the water demand impacts of the Project. Also, the DPEA concludes that water demand impacts are significant, but then fails to propose all feasible mitigation measures. Worsening matters, the DPEA's cumulative impact analysis provides no meaningful assessment of the Project's cumulative water demand impacts. These are clear failures of CEQA requirements. 2-19

Water Quality

The DPEA's conclusion regarding project operational water quality impacts is as follows: "Since all of the affected facilities have been shown under both options of the proposed project to have a potential wastewater increase less than 25 percent, no modifications to any existing wastewater discharge permits are anticipated as a result of the proposed project. Thus, the operational impacts of the proposed project on each affected facility's wastewater discharge and the Industrial Wastewater Discharge Permit are expected to be less than significant." (p. 4-79). What the DPEA did not address is that the installation and use of WGS at the existing glass plant would add a new and different stream to the wastewater. Therefore, the wastewater permit would need to be modified, and the conclusion that the operational impacts are expected to be less than significant is flawed. 2-20

As indicated in our attached September 22, 2010 technical comments, container glass manufacturing operations have experienced significant difficulties in treating the selenium content of wastewater from wet gas scrubbers to meet Regional Water Quality Control Board (RWQCB) industrial wastewater discharge standards. Selenium is used to refine flint (clear) glass container bottles to improve the clarity of the final product. Following the installation of wet gas scrubber technology at the Ball Foster El Monte facility, the facility was unable to comply with its selenium discharge limit. The Ball Foster facility was cited by the RWQCB, and paid substantial fines to settle these violations. Despite a concerted effort and the application of several chemical treatment technologies, the facility was unable to identify a wastewater treatment technology to address these exceedances. As indicated in our technical comments, the Ball Foster facility scrapped the wet scrubber technology, and with the approval of District engineering staff, installed dry scrubber/ESP controls to meet BACT. This effectively eliminated the high-selenium wastewater. The DPEA should therefore properly inform District decision makers of these significant technical challenges associated with treating container glass wet gas scrubber wastewater. In addition, the engineering assessment should not conclude that an expenditure of $225,000 will be sufficient to address high selenium loading in wet gas scrubber wastewater, absent a technical analysis to support this assumption. 2-21

Re: Proposed Amended Regulation XX – Technical Comments - Owens-Brockway Glass Container Inc. Vernon Facility (SCAQMD ID 7427)

Dear Ms. Pham:

By this letter, Owens-Brockway Glass Container Inc. Vernon, California facility (Owens Vernon facility) provides its comments on the August 17, 2010 draft proposed amendments to Regulation XX as presented and discussed during the September 8, 2010 Public Consultation Meeting. Specifically, we provide to the District additional technical information that should be considered in setting Best Available Retrofit Control Technology (BARCT) for glass manufacturing. As summarized below, the Owens Vernon facility has already installed BARCT, which the District has recognized as Best Available Control Technology for the control of sulfur oxides. Our outside technical consultant has found no example of a glass container manufacturing facility with a control configuration as suggested by the December 2008 ETS, Inc. engineering evaluation and the December 2009 District draft staff report. In addition, we have identified numerous technical feasibility issues not considered in the District's analyses to date. Therefore, for the reasons outlined below, the Owens Vernon facility should be excluded from the facilities subject to the SOx shave proposed by the Rule 2002 revisions. 2-22

To put these technical issues in perspective, it is helpful to have an understanding of our plant's customers, employees, and our facility's role in sustainable manufacturing resources in the Los Angeles area. The Owens Vernon facility has been in business for over 70 years. Over the past 25 years, some six individual glass container manufacturing facilities have ceased to operate in the Los Angeles basin, such that the Owens Vernon facility is the only remaining container glass manufacturing facility located within the District. We produce between 2 and 3 million glass bottles per day on five production lines pulling from two furnaces and purchase approximately 330 tons/day of recycled glass. We have 260 employees that represent 15 different countries and territories of origin, over one third of whom have worked at the Owens Vernon facility for over 20 years. The average salary for Owens Vernon staff is three times the minimum wage, 2-23

with medical, dental and pension plan benefits. Our customers are here in Los Angeles; over 75% of our shipments are to customers within 25 miles of the of the Owens Vernon plant. Thus, the Owens Vernon Facility plays a vital role in maintaining sustainable container glass manufacturing in the Los Angeles area.

2-23 Cont'd

It is also important to put our environmental controls into proper perspective. Owens has been an innovator of emission controls on glass manufacturing. At significant cost, our company implemented oxygen-fuel fired glass manufacturing technology to reduce nitrogen oxide emissions from high temperature furnace exhaust. This innovative process control technology was installed to comply with NOx RECLAIM allocations. To comply with SOx RECLAIM, Owens Vernon first employed a SOx control system that injected a water-based sorbent into the exhaust stream prior to the existing electrostatic precipitators (ESPs). However, our facility experienced numerous problems with this technology [*Petition for an Ex Parte, Emergency, and a Short Variance*, Case No. 4472-9, Facility ID 007427, May 15, 1997, paragraphs 6-10]. We also note that the Ball-Foster El Monte facility experienced significant operating problems with its wet scrubber technology, which resulted in the company's decision to replace the wet scrubber with a dry scrubber followed by an electrostatic precipitator [*Petition for Modification and Extension of a Variance*, Case No. 108-20, Facility ID 108701, April 9, 1997, paragraphs 6-14].

2-24

Therefore, with the District's approval, Owens Vernon selected dry scrubbing technology (Trona injection) to reduce sulfur dioxide to comply with RECLAIM. It is important to note that this dry scrubbing technology was identified by the District as Best Available Control Technology (BACT) for the control of sulfur oxides. The dry scrubber controls are followed by the existing three ESPs that operate in parallel to remove entrained Trona sorbent and particulate emissions from the two glass melting furnaces. These technologies reduce sulfur oxide emissions by up to 90%. It is critical to note that the Owens Vernon facility actual SOx emission rate (approximately 0.6 pounds/ton of glass pulled) is significantly lower than the permitted SOx emission rate established for the container glass manufacturing facility in Seattle, Washington that is controlled by the wet scrubber technology evaluated by the District in its BARCT determination.

With this background, we now turn to consider technical issues raised by the District's BARCT analysis that supports the Rule 2002 revisions. As a threshold matter, we know of no container glass facility that currently operates the control configuration that is being proposed as BARCT:

- Dry scrubber/Trona injection, followed by
- Three separate electrostatic precipitators operating in parallel, followed by
- Two wet scrubber (50% NaOH) towers.

The December 2008 engineering evaluation suggests that this is technically feasible and cost effective for the Vernon facility. Owens retained Ashworth Leininger Group (ALG) to review this engineering evaluation, and the technical feasibility of installing retrofit wet scrubber technology at the Vernon facility. Their comments are attached for your review. We note the following:

2-25

- ALG is not aware of any glass manufacturing facility that currently operates with the BARCT control configuration recommended by staff for Owens Vernon: dry scrubbers followed by ESPs followed by wet scrubbers;
- To maintain the current redundancy of controls, which is essential as the glass melting operations cannot be temporarily shut down, it will be necessary to install three wet scrubbers instead of the two suggested in the ETS, Inc. report;
- The ETS, Inc. report does not consider/address how proper operating pressures will be maintained in both the oxy-fuel furnaces and existing ESP controls when the new wet scrubbers are added onto this system;
- The ETS, Inc. report does not address how the integrity of the wet scrubbers will be maintained should there be an upset condition in the ESPs, which will result in high particulate loadings directed to the wet scrubbers;
- The ETS, Inc. report does not properly consider site limitations associated with adding three wet scrubber towers that will be required to control the three existing ESP control systems;
- The ETS, Inc. report does not include all foreseeable costs associated with the wet scrubber retrofits;
- The ETS, Inc report provides no technical analysis of how wastewater discharges will meet RWQCB effluent limitations for selenium and other inorganic compounds;
- If retrofit with wet scrubber technology, the new exhaust gas will have a significantly lower temperature, and therefore significantly reduced plume buoyancy. No modeling analysis has been presented to demonstrate that ambient impacts from the Owens Vernon facility glass manufacturing operations will continue to comply with state and federal ambient air quality standards, including the new short term federal nitrogen dioxide standard; and

- The ETS, Inc. report and District draft staff report/evaluations do not properly consider the acute health risks posed by sodium hydroxide emissions from the wet scrubbers, as required by District Rule 1401.

2-25 Cont'd

Finally, the District's technical analysis does not consider what will happen should the Owens Vernon facility be unable to afford new, yet-to-be demonstrated control configurations, or secure adjusted RECLAIM Trading Credits in sufficient quantities to continue to operate. Should the Owens Vernon facility discontinue operations, over 100,000 tons/year of recycled glass will either have to be landfilled, or shipped out of the basin. Over two to three million glass containers per day will have to be shipped into the basin to our customers. We believe that this issue, along with the land use impacts associated with urban decay resulting from our plant's potential closure and adverse impact on environmental justice areas should be addressed in the District's Program Environmental Assessment for the proposed rule change. Our formal comments on that document will be provided by October 1, 2010.

2-26

We recognize that these comments are provided at the end of this public comment period for Rule 2002 modifications. If you think helpful, we would be willing to meet with you to clarify our comments. We look forward to working with the District to finalize Rule 2002 amendments.

Very truly yours,

Dean Harris

Ashworth Leininger Group Comments on Proposed Amended Rule 2002
On Behalf of Owens-Brockway Glass Container Inc.

Ashworth Leininger Group (ALG) was retained by Owens-Brockway Glass Container Inc. (Owens) Vernon facility to review the August 17, 2010 draft Rule 2002 rule modifications, and data provided by the South Coast Air Quality Management District (District) staff at the September 8, 2010 Public Consultation meeting[1]. Comments 1-3 address proposed amended Rule 2002 revisions; comments 4-8 address technical issues associated with the Best Available Retrofit Control Technology (BARCT) analysis.

Specific Comments on Proposed Amended Rule 2002:

1. Owens-Brockway should be included in the list of SOx RECLAIM holders exempted from proposed "shave". As discussed further below, Owens Vernon has already installed dry scrubbing technology considered by the District to be Best Available Control Technology (BACT). Further, there are unique site conditions that have not been fully evaluated in the December 2008 ETS, Inc. engineering report, and make installation of additional retrofit controls infeasible. Since additional SOx controls are infeasible (as discussed below), it is inappropriate to subject Owens to the same SOx shave requirements as the other ten SOx RECLAIM participants impacted by section (f)(1)(J). For these reasons, the Owens Vernon facility should be added to Table 5 that lists the RECLAIM facilities that are exempted from the proposed SOx RTC adjustments ("shave") described in section (f)(1)(J). 2-27

2. Table 4 should be revised to remove the Best Available Retrofit Control Technology level for container glass melting furnaces. As discussed in more detail below, Owens has already installed dry scrubbing technology equivalent to what should be considered as Best Available Retrofit Control Technology (BARCT) to reduce container glass furnace SOx emissions. As discussed below, the District's evaluation of wet gas scrubber (WGS) controls with respect to the existing Owens facility process and control configuration did not properly consider the technical and operational issues associated with installing retrofit WGS controls in conjunction with existing dry scrubbers and electrostatic precipitators. The evaluation did not consider the need to install three, not two, WGS units, nor physical site limitations with respect to installing three new WGS units (in addition to the existing two dry scrubbers and three ESPs.) The District's evaluation also 2-28

[1] The rule development history for the proposed amended Rule 2002 is somewhat complex and lengthy. Briefly, Table 4 of Proposed Amended Rule 2002 indicates that BARCT for container glass melting furnaces is a SOx emission rate of 5 ppm, equivalent to 0.03 pound of SOx per ton of glass pulled. The District's December 2009 *Draft Staff Report for Proposed Amended Regulation XX* identifies this as representing 95% control from Owens' 2005 SOx emission rate of 0.62 pound per ton of glass pulled. As the final BARCT study report indicates, emissions at the Owens facility are already controlled with two dry scrubbers, followed by three electrostatic precipitators (ESPs). Based on information presented by the District at its September 8, 2010 SOx RECLAIM Public Consultation Meeting, Tier I BARCT had previously been determined to be the 1993 average Reported Value of 2.51 pounds SOx per ton of glass pulled; therefore the proposed BARCT level represents a 99% reduction in SOx emissions.

did not consider the severe operational difficulties encountered by another container glass manufacturer when it attempted to operate a WGS in conjunction with an oxy-fueled glass furnace. As described below, the engineering analysis did not fully calculate the cost of WGS retrofits and RECLAIM compliance modifications. Considering these issues, BARCT for container glass melting furnaces should not be established any lower than presently achieved at Owens with its dry scrubbers operated in conjunction with ESPs.

2-28 Cont'd

3. Section (f)(1)(Q) should be clarified to indicate that it applies only to new SOx RECLAIM program entrants. Rule 2002 section (f)(1)(Q) provides that:

> "SOx Allocations for compliance years 2012 and after, for facilities that enter RECLAIM after (date of adoption) and for basic equipment listed in Table 4 shall be determined according to the BARCT level listed in Table 4 or the permitted emission limits, which ever is lower."

2-29

Section (f)(1)(Q) should be clarified to indicate that SOx allocations for facilities entering RECLAIM after rule adoption (new facilities) with equipment listed in Table 4 will receive allocations for 2012 and later based on the BARCT limits in Table 4 or based on permitted levels (whichever is lower). As written, section (f)(1)(Q) could be interpreted as also requiring allocations for existing facilities with basic equipment listed in Table 4 be reduced to Table 4 BARCT levels effective 2012, which runs contrary to the provisions of proposed sections (f)(1)(I) and (f)(1)(J).

Specific Comments on Best Available Control Technology:

The Owens Vernon facility operates two oxy-fuel furnaces (Furnace B, rated at 60 MMBtu/hr, and Furnace C, rated at 100 MMBtu/hr). These two process units are controlled by dry scrubber sorbent (Trona) injection, followed by three 3-field electrostatic precipitators (ESPs) which remove the sorbent and particulate emissions associated with glass melting. The use of three ESPs is required to provide redundancy in controls, as the underlying equipment (glass melting furnaces) cannot be shut down. Furnace B has a permitted SOx emission rate of 3.15 pounds SOx/ton of glass pulled; Furnace C has a permitted SOx emission rate of 2.4 pounds SOx/ton of glass pulled.

2-30

Following the adoption of RECLAIM, the facility first installed a United McGill semi-dry SOx scrubber on Furnace B in 1994. This control configuration proved infeasible in the long term due to maintenance and operational issues, as agreed to by the District Hearing Board, and was subsequently replaced by a dry scrubber, which was optimized through the use of Trona sorbent materials. Testing on the unit demonstrated up to 90% control efficiency relative to SOx; however, the systems typically operate at a 75-85% control level. With this general background, we provide specific comments related to the District's BARCT evaluation and proposed control level:

4. The emission reductions associated with the specific combination of controls relied upon by the District to achieve its proposed BARCT level has not been achieved in practice. We know of no installation in which a facility relies upon dry scrubbing, dry ESPs, followed by wet scrubbing to achieve the emission reductions anticipated by the District. Further, we have talked to equipment vendors, engineering/environmental staff at glass manufacturing facilities, and independent consultants, and they are aware of no such control configurations. We anticipate such a combination of controls would encounter the following challenges:
    - There is no discussion as to why two wet scrubbers (with a combined capacity of 60,000 cfm) are to be applied to control emissions from three ESPs (with a combined capacity of 90,000 cfm). To maintain the quick dispatch, operating pressures (addressed further below) and current redundancy in the existing control configuration, a single wet scrubber is required to follow each ESP. Thus, three wet scrubbers will be required to support the Vernon facility, as opposed to the two units considered in the ETS, Inc. analysis.
    - Pressure drop over the dry scrubber and dry ESP stages could preclude the wet scrubber stage from achieving the anticipated SOx removal efficiencies, and unless properly managed, can adversely affect the operation of the oxy-fuel furnace itself. Management of the furnace operating pressures and pressure drop across all three controls (Trona injection, ESP, wet scrubber) would require use of variable fans/process controls that are not addressed in the December 2008 ETS, Inc. report. Failure to properly maintain pressures throughout the system will compromise the furnace operation (including potential catastrophic failure), particulate control and sulfur oxide control efficiencies. In addition to these technical issues, the costs for viable induction fan motors/drives and process controls do not appear to have been considered.
    - Injection of sodium sesquicarbonate (Trona) in the dry scrubber stage results in increased particulate loading that is removed by three ESPs operating in parallel. While there is redundancy in the use of three ESPs, the ESP control units break down and when this occurs, increased particle loading to be routed directly to the wet scrubbers would occur at an uncontrolled rate of 120-150 pounds/hour. No discussion is provided as to how the wet scrubber technology will be protected when there is an upset condition in the Trona injection/ESP operation. This is a significant issue as high particulate loading will foul and compromise the wet scrubber technology.
    - We note that the particulate loading design value provided by ETS to the various equipment vendors understated the particulate loading allowed by the permit by an order of magnitude (0.008 grains/dry standard cubic foot cited in the ETS report versus the permit limit of 0.08 grains/dry standard cubic foot). The ETS, Inc. analysis should be corrected, and vendors contacted to assure that increased particulate loading can be accommodated by the wet scrubber technology.
    - Selenium is present in Owens' exhaust gas. Large quantities of water will be required to cool the exhaust gas to the temperature range required for the wet scrubbers, as well as for operation of the wet scrubbers. This water will require

2-30 Cont'd

treatment to remove the selenium prior to off-site disposal. There is no detailed analysis of the technical feasibility to treat this stream; rather the ETS, Inc. report assumes that one of four options is feasible at a cost of $225,000, which in our view ignores technical issues and simply throws money at the problem without solving this issue. As an example, one of the options proposed in the ETS report for treating wastewater (Option 3 on page 6 of the ETS report) is to send blowdown from the scrubbers to a storage tank and then spray it into the duct ahead of the precipitators to evaporate the water and collect the dry particulate in the ESPs. This does not account for the PM loading to the ESPs associated with Trona injection, does not address whether the exhaust temperature will be sufficient to support evaporation of the water, nor does it account for the potential issues associated with adsorption/absorption of the water by the Trona and particulate matter.

Owens encountered a nearly identical situation in 1997, when it experienced moisture buildup in the ESPs resulting in short-circuits within the units, as a result of water injection prior to the ESPs and insufficient temperatures to evaporate the water. At the time, Owens was operating a semi-dry scrubber on Furnace B, in which soda ash and water were injected into the furnace exhaust prior to the ESP. Previously, Owens had been operating three furnaces, and the combined exhaust temperature was sufficient to support evaporation of the injected water. However, once Furnace A was shut down, exhaust temperature dropped, resulting in condensation buildup in the ESPs. The condensation buildup, combined with the ESP dust, became acidic and corroded wiring within the ESPs. Acidic water also began leaking outside the ESPs, necessitating additional abatement efforts. Owens attempted to prevent heat loss by adding insulation on the ducting, which proved insufficient. Owens also considered raising the scrubber exhaust temperature, but recognized that this was infeasible since it would require reducing the exhaust gas residence time and reduce the scrubber control efficiency [*Petition for an Ex Parte, Emergency, and a Short Variance*, Case No. 4472-9, Facility ID 007427, May 15, 1997, paragraphs 6-10].

2-30 Cont'd

- We note that the Ball Foster El Monte facility was unable to achieve compliance with its selenium discharge permit limits when operating a wet scrubber. Based on discussions with former company staff, high selenium concentrations in wastewater discharge resulted in non-compliance penalties and was a key consideration in the decision by the company to switch to dry scrubber control technology.
- No analysis is provided of the acute health risk posed by emissions of 50% NaOH scrubber mist that will be released from the operation of the three wet scrubbers, and whether this incremental acute health risk is within District Rule 1401 requirements. The District's CEQA analysis improperly focuses on storage of sodium hydroxide, and fully ignores emissions from the wet scrubber stack. As indicated below, this toxics analysis is especially important, as the wet scrubber controls require that exhaust temperatures be reduced to ~150

degrees F. This lower exhaust temperature will reduce the buoyancy of the plume, and increase ambient concentrations near the facility.

- No analysis has been performed to show compliance with the new federal ambient standard for nitrogen dioxide. The wet scrubber technology requires that the temperature of the exhaust gas has to be reduced from 650 degrees F to ~150 degrees F. This significant reduction in exhaust temperature will significantly reduce the buoyancy of the plume, and thus increase ambient concentrations of exhaust gases, including nitrogen dioxide, particulate, air toxics, and combustion gases. This refined analysis must be performed as it will be required by the District.
- As we will comment as part of the CEQA documentation, the District has not evaluated the ability to introduce a new hazardous material (50% sodium hydroxide solution) into a manufacturing process consistent with the California Legislature's directive under the new Green Chemistry Initiative, which will be in effect when SOx emission reduction process modifications will be made.

5. Adding a wet scrubber stage to the Owens SOx emissions control system is technically infeasible. Beyond the technical issues identified in the immediately preceding comment, Owens will encounter the following issues which preclude addition of a wet scrubber stage:
   - There is insufficient space next to the existing controls to install three wet scrubbers, stacks, and necessary support equipment adjacent to the existing facility. As explained to ETS at the time of their site visit, there is a single 14'x22' pad proximate to the existing three ESPs. In our experience, this is insufficient to locate three wet scrubber towers rated at 30,000 cfm each, and associated pumps/Continuous Emissions Monitoring Systems (CEMS) and related process equipment.
   - Owens would have only two options for installing the required wet scrubber controls: 1) installing the control systems in its parking lot located to the east of the existing ESPs and running ducting over the top of a building (which would pose unacceptable safety issues); or 2) tearing down a building. No cost/feasibility analysis was provided for these two options.

2-30
Cont'd

6. Costs associated with BARCT for container glass melting furnaces is understated. Costs are underestimated for the following reasons:
   - As previously stated, BARCT for container glass melting furnaces is currently established at a level of 2.51 pounds of SOx per ton of glass pulled. Based on the District's evaluation of BARCT, achieving the proposed BARCT level of 0.03 pound SOx per ton of glass pulled would require a combination of dry scrubbers, dry ESPs, and wet scrubbers. Therefore, at a minimum, the costs for all three technologies need to be incorporated into the cost-effectiveness analysis.
   - The BARCT cost estimates need to account for three wet scrubbers and associated ducting/support equipment as each ESP will require a dedicated wet scrubber to maintain needed control redundancy for the oxy-fuel furnaces.

- As indicated above, the ETS report provides no basis for the estimated $225,000 in capital costs associated with wastewater treatment, which can be significant as selenium is especially hard to treat to RWQCB discharge limits.
- No costs are provided for the construction of three new exhaust stacks, for relocation and installation of the CEMS on each of these three stacks, for permitting of the CEMS with the District's RECLAIM group, for the new Relative Accuracy Test Audits that must be performed, or for the costs of RTCs to cover the missing data that will be recorded by the new CEMS. Our prior experience on CEMS monitoring systems indicates that costs for three such systems can exceed $250,000 for each CEMS.
- No technical data are provided to support the estimated 25-year useful life of a caustic wet scrubber. Our experience with caustic wet scrubbers suggests a shorter useful life (10-15 years), which is also typical of useful life assumptions based on EPA and other local air district control technology analyses.

7. <u>The District did not consider the implementation challenges faced by Ball-Foster when attempting to utilize a wet scrubber to control SOx emissions from an oxy-fueled glass furnace in the mid-1990s</u>. In February 1995, Ball-Foster converted its regenerative glass furnace to oxy-fuels operation at its El Monte facility. Previously, the furnace had utilized a venturi wet scrubber to control PM emissions. After the conversion, Ball-Foster reconnected the furnace to the wet scrubber. Starting one month later, the scrubber began experiencing numerous equipment failures, including component overheating and damage, plugging, and excessive solids buildup – prompting numerous emergency breakdowns. After struggling with the scrubber operational problems for a year, Ball-Foster informed the District Hearing Board that it intended to replace the wet scrubber with an ESP to control particulate emissions, and a dry scrubber to control SOx emissions. By mid-1997, the wet scrubber had been removed and replaced by a dry scrubber and ESP [*Petition for Modification and Extension of a Variance*, Case No. 108-20, Facility ID 108701, April 9, 1997, paragraphs 6-14]. Like the Ball-Foster furnace, both of Owens' glass furnaces are oxy-fuel fired.

8. <u>BARCT for container glass meting furnace SOx emissions should be established as the emission rate achievable by Owens' current dry scrubber/ESP control system</u>. Based on information presented in the District's December 2009 Draft Staff Report, this would be a level of between 0.62 and 1.05 pounds SOx per ton of glass pulled, and represent the combination of process modifications and control technology. Notably, this SOx emissions limit is below the permitted SOx emission rate (1.6 pounds SOx/ton of glass pulled) established for the Seattle, Washington container glass plant that that is controlled by the wet scrubber technology evaluated by the District in its BARCT determination.

Responses to Comment Letter #2
(Owens-Brockway Glass Container, October 1, 2010)

2-1 Individual responses to the technical issues and background comments submitted have been prepared and begin with Response to Comment 2-3. Regarding the claim that the facility is already at BARCT, see Response to Comment 2-4.

2-2 Owens-Brockway Glass Container Inc. (Vernon Branch) is a subsidiary of Owens-Illinois, Inc. According to the website for Owens-Illinois, the parent company of Owens-Brockway, in 2009 Owens-Illinois had 22,000 employees in 21 countries with net sales of $7.1 billion[1] and a gross profit margin of 21 percent. SCAQMD records confirm that Owens-Brockway is the only glass container facility in the district.

According to the proposed amendments, there is an adequate amount of RTCs in the current SOx RECLAIM market that affected facilities could use. Currently, the surplus of RTCs in 2005 is about 1.73 tons per day and the surplus of RTCs in 2008 is about 2.55 tons per day (out of total RTC holdings of 11.77 tons per day). The amount of RTCs converted from ERCs contributed to the size of the surplus. In addition, the amendments instituted several safety valves to prevent potential facility shutdowns: 1) gradual annual reductions with extended compliance schedule (2012-2019); 2) monitoring of RTC price trend (12 month rolling average), 3) hold Public Hearing if RTC price exceeds $50,000 per ton (discrete price), 4) ability for Governing Board to set aside (give back) up to 100 percent of RTC reductions for any year when RTC price exceeds $50,000 per ton.

Based on the Staff Report the cost-effectiveness for the glass plant is estimated to be $9,000 per ton of SOx reduced. The average annual cost of complying with the proposed requirements is estimated to be $0.52 million (socioeconomic report). Based on the above assumptions, Owens-Brockway Glass Container facility is not expected to shutdown due to the requirements of the proposed amendments.

2-3 The particulate buildup problems that Owens-Brockway and Ball-Foster Glass Container encountered between 1994 and 1997 are not expected to occur with the WGSs proposed by the consultant ETS Inc. (ETS) because ETS proposed to remove the two existing dry gas scrubbers located upstream of the ESPs and replace them with two WGSs located downstream of the ESPs. The ESPs located upstream of the wet gas scrubbers will collect particulate matter and prevent excessive particulate buildup in the wet gas scrubbers. In addition, fine powder Trona injection needed for the dry gas scrubbers would no longer be needed, and thus any Trona leakage to the ESPs would drop to zero, and the particulate loading to the ESPs would be reduced significantly. Detailed explanations on the problems occurred at Owens-Brockway and Ball-Foster Glass Container encountered between in 1994 and 1997 are presented in the following paragraphs.

Owens-Brockway

Owens-Brockway currently operates two oxy-fuel furnaces (Furnace B, 60 MMBtu/hr, and Furnace C, 100 MMBtu/hr). Previously, Owens-Brockway operated three furnaces

[1] O-I Announces Third Quarter Earnings Conference Calland Webcast, September 20, 2010. http://www.o-i.com/nth_us.aspx?id=400; http://www.o-i.com/about_oi.aspx?id=1348 and http://www.o-i.com/nth_us.aspx?id=400

(Furnace A, B and C). In 1974, Owens-Brockway installed a United McGill semi-wet scrubber using soda ash as the scrubbing agent to control SOx. The particulate matter emissions from the three furnaces are controlled by three ESPs located downstream of the semi-wet scrubber (any two ESPs are in operation at one time, while one ESP is stand-by.) As explained by Ashworth Leininger Group (ALG), Owens-Brockway experienced numerous problems with the semi-wet scrubber and ESPs because during a period when one of the furnaces (Furnace A, non-oxy fuel furnace) was shutdown in December 1996, the exhaust temperature dropped, resulting in condensation buildup in the ESPs. ALG further explained that the condensation buildup caused corrosion within the ESPs. For this reason, Owens-Brockway had to seek several variances from the SCAQMD Hearing Board in 1997 and finally decided to remove the semi-wet scrubber and replaced the semi-wet scrubber with the two dry gas scrubbers. Trona, a very fine powder, is currently used as sorbent in the dry gas scrubbers.

SCAQMD staff believes that the problems with the semi-wet scrubber and ESPs were not caused by equipment capability, but equipment operation. Condensation problems would not have occurred in the ESPs if Furnace A were not shut down and the temperature of the flue gas entering the ESPs was high enough to prevent moisture condensation in the ESPs. The following, excerpted from Owens-Brockway Glass Container Corp.'s May 14, 1997 Petition for an Ex Parte, Emergency, and a Short Variance (Case No. 4472-9) supports SCAQMD staff's position:

> *"Prior to discontinuing the operation of Furnace A, the temperature of the combined exhausts from Furnaces A and C, when mixed with Furnace B exhaust, was high enough to keep the exhaust moisture content as vapor in the ESP. Since Petitioner has only been operating Furnaces B and C, the volume of exhaust has been reduced and the combined exhaust temperature has not been high enough to keep exhaust mixture in the form of vapor as exhaust enters the ESPs. Consequently, moisture condenses in the ESPs."*

Ball-Foster Glass Container

The problem that occurred at Ball-Foster Glass Container (aka Saint-Gobain Containers) was very different in nature than the problem that occurred at Owens-Brockway. Ball-Foster Glass Container did not use ESPs to control particulate matter. They operated a wet venturi, variable throat scrubber using soda ash as absorbent to control both SOx and particulate matter. In 1993, they converted their existing glass furnace to an oxy-fuel furnace which was operated with significantly less combustion air, which subsequently resulted in reducing the volume of exhaust flue gas from the furnace to the venturi scrubber and increasing the particulate loading to the scrubber. SCAQMD staff believes that the excessive solids build-up in the scrubber system was due to failure to redesign the venturi wet scrubber to handle the excessive particulate loading after the conversion to the oxy-fuel furnace. In 1999, Ball-Foster Glass Container removed the venturi wet scrubber and replaced it with a dry gas scrubber to control SOx and an ESP to control particulate matter.

2-4 Control technology has improved over time. The dry gas scrubbers operating at 80 percent to 90 percent control efficiency were considered as BARCT for SOx in 1994. However, between 2008 and 2010, two consultants (ETS and NEC) expressed agreement that non-regenerative wet gas scrubbers can achieve a range from 1 ppmv to 5 ppmv SOx outlet concentration (95 percent control efficiency or more from the 2005 emissions baseline, 99 percent from the uncontrolled level assuming that the dry gas scrubbers operated at 80

percent control efficiency) and thus, should be considered as BARCT for SOx for glass melting furnaces. While these two consultants recommended different types of WGSs, however, they both concurred that WGSs would be cost-effective and SCAQMD staff concurs with the consultants' recommendations. The two consultants both recommended keeping the existing ESPs in place for particulate control and placing the wet gas scrubbers downstream of the ESPs.

In addition, the proposed BARCT level for glass melting furnaces has been achieved in practice. Specifically, the Puget Sound Clean Air Agency in Seattle, Washington provided SCAQMD staff with source test and CEMS data from Saint-Gobain, a glass container facility, that demonstrates compliance with 5 ppmv SOx levels (96 percent control) via Tri-Mer's Cloud Chamber scrubber. The furnace at Puget Sound has a permit limit of 1.6 pounds of SOx per ton of glass pulled but tested at 0.0062 pound of SOx per ton of glass pulled [2, 3]. SCAQMD staff had multiple conversations with Tri-Mer about their WGS technology, and Tri-Mer indicated to SCAQMD staff that they provided many types of WGS that can be used to achieve 5 ppmv SOx outlet concentration, either packed bed, open throat, venturi, or Cloud Chamber scrubber. The Cloud Chamber scrubber can also be used as a particulate control device.

The commenter has indicated that dry gas scrubbers can achieve up to 90 percent control. It is interesting to note that Owens-Brockway currently holds 0.31 ton per day of RTCs. With the proposed RTC shave of 55 percent, Owens-Brockway remaining allocations would be 0.14 ton per day. The 2005 emissions from Owens-Brockway were about 0.2 ton per day at 80 percent control[4]. Thus, if the control efficiency of dry gas scrubbers were improved to 90 percent as the commenter notes is achievable, then Owens-Brockway would already be in compliance with the shave at 0.1 ton per day of SOx emissions[5]. However, if Owens-Brockway operators choose to install wet gas scrubbers, surplus RTCs will be created that could be sold when needed.

2-5 Regarding the comment that the Draft PEA does not demonstrate that adequate water supplies are available, see Responses to Comments 3-14, 3-19, 3-29, 3-31, 3-43, 3-45, and 3-46.

2-6 The Draft PEA concludes that the water demand impacts are significant for potable water demand, not total water. Thus, mitigation measures HWQ-1 and HWQ-2 are designed to minimize the use of potable water by utilizing recycled water instead. The SCAQMD has identified no other feasible mitigation measures (or alternatives) that would mitigate to less than significance the need for potable water. While arguing that the SCAQMD has not required all feasible mitigation, the comment fails to identify any additional measures. With regard to the content of the cumulative water demand impacts discussion, CEQA Guidelines §15130(b) requires the discussion of cumulative impacts to reflect the severity of the impacts and the likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. SCAQMD staff

[3] CEMS Summary Report from Saint-Gobain to Puget Sound Clean Air Agency, for a period from October 1, 2009 to October 31, 2009.

[4] SCAQMD Engineering Evaluation, A/N 288744, March 1994.

[5] 80% control of 1 ton per day = 0.2 ton per day, and 90% control of 1 ton per day = 0.1 ton per day

believes the cumulative water demand impacts discussion in the Draft PEA adequately describes why they are considered to be cumulatively considerable. For additional information, refer to Chapter 5 of the PEA.

2-7 The commenter does not provide any information or other data demonstrating why the analysis of the GHG impacts and the corresponding mitigation measures are inadequate. The Draft PEA contains a detailed discussion of the GHG impacts which is supported by the extensive calculations in Appendix B. Because the GHG emissions estimates exceed the SCAQMD's CEQA significance threshold of 10,000 MTCO2eq/yr, the impacts were concluded to be significant and all feasible mitigation measures were identified. See also Responses to Comments 3-9, 3-39, and 3-40.

2-8 The range of alternatives evaluated in a CEQA document must be sufficient to permit a reasoned choice, but need not include every conceivable project alternative. CEQA Guidelines §15126.6(c) specifically notes that the range of alternatives required in a CEQA document is governed by a 'rule of reason' and only necessitates that the CEQA document set forth those alternatives necessary to permit a reasoned choice. The key issue is whether the selection and discussion of alternatives fosters informed decision making and meaningful public participation. A CEQA document need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative. SCAQMD Rule 110 (the rule which implements the SCAQMD's certified regulatory program) does not impose any greater requirements for a discussion of project alternatives in an environmental assessment than is required for an EIR under CEQA. The commenter's suggestion that the alternatives analysis is inadequate because none, other than Alternative A, the 'no project' alternative, specifically addresses glass manufacturing, represents a misunderstanding of the RECLAIM program. Under RECLAIM, a facility may purchase RTCs in lieu of installing control equipment. Thus, the proposed project and each of the alternatives potentially affect the subject facility because it as an affected RECLAIM facility and are evaluated as part of an overall regulatory program, which is why a Program EA was prepared. As part of a regulatory program, a smaller shave, for example, would reduce compliance obligations for all facilities that would be subject to the proposed project. Moreover, Alternative A is a required alternative (CEQA Guidelines §15126.6(e)). Finally, CEQA requires a range of reasonable alternatives (CEQA Guidelines §16126.6(a)), which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives. The alternatives identified and evaluated for the proposed project comply with this and all other applicable CEQA requirements.

The NOP/IS prepared for the proposed project solicited suggestions for alternatives for the proposed project. Owens-Brockway did not submit any comments on the NOP/IS. Similarly, the commenter did not provide any specific recommendations for any alternatives beyond those evaluated in the PEA.

2-9 The commenter has misunderstood the assumptions about the timing with regard to facility operators implementing the proposed project. Under the RECLAIM program, facilities have the flexibility to install air pollution control equipment, change method of operations, or purchase RTCs to meet BARCT levels. As such, the Draft PEA has been crafted to explore multiple scenarios that illustrate the worst-case effects of applying the various SOx

control technologies along with demonstrating the flexibility that is provided by the RECLAIM program to facility operators when it comes to choosing the methods for reducing SOx emissions. Because of the program's built-in flexibility, as a practical matter, there is no way to predict what each facility owner/operator will do. However, not all of the affected facilities will need to take immediate action to comply with the proposed project.

The survey conducted by the consultants identified likely technologies that could be used to comply with reducing SOx emissions in connection with amending SOx RECLAIM rules. The following SOx control technologies were identified and environmental impacts of constructing and operating these equipment were analyzed in the PEA: WGSs, dry gas scrubbers, fuel gas treatment, SOx-reducing additives, et cetera. The focus of the environmental analysis is on WGS because their size and operating characteristics typically generate a greater number of or more substantial impacts than the other technologies (e.g., construction air quality impacts, water and hydrology impacts, et cetera).

If a facility operator chooses to install air pollution control equipment such as a WGS, the consultants' reports estimate that 18 months would be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and lining up contractors and workers. Further, to physically build a WGS, the consultants' reports indicated that an additional 18 months would be needed. The Draft PEA considers the overlapping construction of building four WGSs within the same 18-month period. This overlap could occur anytime between the date of adoption (scheduled for November 5, 2010) and full implementation (January 1, 2019). However, as a practical matter, even if a facility starts the planning and engineering process now (at the time of this writing October 2010) to design a WGS installation (and some are in the very early pre-planning stages), construction is not expected to occur sooner than 2012. For these reasons, the Draft PEA considers <u>any</u> 18-month window between January 1, 2012 and January 1, 2019 (a span of seven years) when facilities could undergo construction activities. These dates correspond to the final compliance date for the proposed project (January 1, 2019) and the first year when the RTC shave will occur (2012). Thus, the analysis in the Draft PEA has demonstrated that the peak daily construction could not reasonably occur in year 2011.

2-10 In response to the comment about the availability of wet gas scrubbers, the consultants' worked with multiple manufacturers of wet gas scrubber technology and none of the manufacturers indicated that there would be a problem with the supply chain. In response to the comment that the Draft PEA should analyze the possibility where facilities would install SOx controls within a two-year period and not a seven-year period, see Response to Comment 2-9. For a discussion about "reasonable worst case" assumptions consistent with the CEQA Guidelines, see Response to Comment 3-19.

2-11 Individual responses to the detailed comments submitted per environmental topic have been prepared and begin with Response to Comment 2-12.

2-12 While the comment states that there are no visible steam plumes at the glass melting plant or in the immediate area, SCAQMD records[6] show that there are at least three cooling towers, which are sources of steam plumes, at Owens-Brockway and at two neighboring facilities within one mile of Owens-Brockway (Henry Company located at 5731 Bickett in Huntington Park and the Seven-Up/Royal Crown Bottling Company located at 3220 East 26th Street in Los Angeles). Cooling towers, essential to industrial and commercial processes that require heat dissipation, utilize an open wet system that relies on the latent heat of water evaporation to exchange heat between the process and the air passing through the cooling tower. As the water evaporates, a stream of saturated exhaust air, a steam plume, leaves the tower. The plume is visible when the water vapor it contains condenses in contact with cooler ambient air. Depending on a cooling tower's location and the surrounding atmospheric conditions such as temperature and humidity, i.e., in an area of typically high humidity and low temperatures (near the coast) versus an area of typically low humidity and high temperatures (inland desert areas), this water-saturated air can create a visible plume.

In addition to the aforementioned facilities, there is another facility, as shown in the following satellite photo, located near the corner of 50th Street and Seville Avenue in Vernon, approximately one block away from the glass melting plant, that currently has three visible steam plumes (as identified by the ellipse) emanating from three cooling towers[7]. These plumes are also part of the existing aesthetics setting of the area surrounding the Owens-Brockway facility. This means that if all of the cooling towers are operating, depending on the ambient temperature and humidity, visible steam plumes may be present at or throughout the area near the Owens-Brockway facility. However, as noted in the Final PEA and as illustrated in the following satellite photo, because of the existing plumes, one additional plume from each WGS installed is not expected to significantly adversely affect the visual continuity of the surrounding area of each affected facility because no scenic highways or corridors exist within the areas of the refineries, the coke calciner, the sulfuric acid plants and the glass melting plant. Further, because the plume from a new WGS is located in an industrial area and would likely be located approximately the same distance from residences, approximately ¼- mile away, compared to the existing plumes from the cooling towers, it would be no more noticeable to the closest residents than the existing plumes. Therefore, the conclusion that aesthetics impacts from implementing the proposed project would be less than significant continues to be valid.

A = Owens-Brockway, located at 2901 Fruitland Avenue, Vernon, CA

2-13 The air quality impact analysis provided by the commenter relied on USEPA's SCREEN3 model using standardized operating conditions with the primary adjustment for exhaust temperature due to the installation of WGSs. SCREEN3 is a very conservative tool used to calculate the "worst case" one-hour maximum ground level concentration from an emissions source. The impact predicted from SCREEN3 is the 100th percentile concentration. While the analysis uses the recommended 75 percent conversion rate from NOx to NO2, the predicted NO2 continues to represent the 100th percentile concentration and is not consistent with the form of the standard. The current NAAQS for NO2 is based on the three-year average of the 98th percentile of NO2. As a consequence, the predicted SCREEN3 modeled concentrations do not conform to the standard and are expected to overestimate the ground level impact.

The analysis used the three-year average 98th percentile NO2 concentration measured at Central Los Angeles (158 µg/m^3, 2006-2008) as the background to be added to the ground level impact. While the selection of Central Los Angeles NO2 as background was correctly assumed, it is important to note that construction and operation of the WGSs are not expected to occur before 2011. The analysis in the Draft PEA assumes the earliest that installation of WGSs could occur would be in 2012, but installations may occur anytime between 2012 and 2019. Ambient averages of NO2 have decreased since 2000 in the Basin and at Central Los Angeles. Three-year averages of the annual average and one-hour maximum NO2 concentrations from 2000-2002 through 2006-2008 have been reduced by 22 and 25 percent, respectively. Regional NOx emissions were reduced by 22 percent for the same period. Implementing the 2007 AQMP together with ongoing NOx emission reductions from mobile sources is projected to continue the trend of lower NOx emissions

reductions in future years. This trend will result in lower ambient NO2 concentrations throughout the Basin. Implementing the 2007 AQMP together with ongoing reductions in mobile source NOx is projected to continue the trend of lower NOx emissions in future years. This will result in lower ambient NO2 throughout the Basin. Using the 2007 AQMP NOx emissions inventory, an emissions-weighted projection of NO2 at Central Los Angeles is estimated to be reduced by approximately 17 percent from 2008 to 2012. Furthermore, the projection to 2019 estimates that the NO2 concentration should be lowered by 34 percent compared with the 2008 values.

When a 2012 estimated background is applied to the "worst-case" SCREEN3 modeling analysis provided, the impacts from the exhaust streams from the furnaces (153 $\mu g/m^3$ without WGSs and 168 $\mu g/m^3$ with WGSs) would not exceed the NO2 standard. If construction of the WGSs is delayed until after 2012, the impacts would be even lower and the NO2 standard would continue to be met.

2-14 Although the CAPCOA document was not released until August 2010, staff evaluated the mitigation measures in that document to identify feasible mitigation that could further reduce the program level GHG impacts from the proposed project. The CAPCOA document groups related mitigation measures under general categories similar to the environmental topic categories on the environmental checklist (CEQA Guidelines Appendix G) to facilitate identification of mitigation measures that might apply to those environmental topics. The results of staff's review of the CAPCOA document are provided in the following bullet points.

- Energy – Energy mitigation measures in the CAPCOA document are divided into three categories: building energy use; alternative energy generation; and lighting. Building mitigation measures do not apply to the proposed project because they consist of energy efficiency strategies that do not apply to industrial facilities like those affected by the proposed project, e.g., energy efficient appliances, etc. Alternative energy generation strategies are not feasible because there may be space limitations, e.g., solar panel arrays, the strategies are not applicable to the affected facilities, e.g., methane recovery in landfills, or they may generate environmental impacts that were not evaluated in the PEA. Lighting mitigation strategies refer primarily to street lighting which is not within the SCAQMD's authority to require or enforce.

- Transportation – Transportation mitigation measures in the CAPCOA document are divided into seven subcategories. Transportation strategies such as increased diversity of the urban land for suburban developments, integrated affordable housing below market rate housing, provide traffic calming measures, incorporate bike lane street design, implement market price public parking (on-street), provide transit access, improvements, install park-and-ride lots, electrify loading docks, etc., are not applicable to the proposed project; would typically be implemented by cities, counties, or transit agencies; and are not within the SCAQMD's authority to require or enforce.

- Water – Water use mitigation measures in the CAPCOA document are divided into two subcategories: water supply and water use. Under water use, the use of recycled water is consistent with water-related mitigation measures, GHG-1, already required as a mitigation measure to reduce GHG impacts. Using recycled water reduces GHG emissions because less energy is required to collect, treat, and redistribute to the point of

use. Water use mitigation measures are generally not applicable to industrial facilities, e.g., design water-efficient landscapes, reduce turf in landscapes and lawns, etc.

- Area Landscaping – The three area landscaping mitigation measures are generally not applicable to industrial facilities because such facilities tend to be devoid of landscaping to reduce fire hazards.

- Solid Waste – The solid waste mitigation measures are not generally applicable to the proposed project, e.g., institute or extend composting services. Recycling demolition materials may be a possible mitigation measures, but demolition is not expected to generate large enough volumes of waste that recycling would generate substantial reductions in GHG emissions.

- Vegetation – Of the two mitigation measures under vegetation the measure to create vegetated open space may not be feasible because of safety concerns (see area landscaping) and the industrial facilities may not have space. Although urban tree planting is a potential option, the cost effectiveness of this measure ranges from $145 per metric ton (with synergistic energy benefits) up to $1,276 per metric ton (without the energy effects)8. Given that GHG emission impacts from the propose project were calculated to be 38,771 MTCO2 per year, to reduce impacts to less than significant, 28,772 MTCO2 per year for 30 years (the life of the project), would need to be reduced making this mitigation measure cost-prohibitive and, therefore, infeasible.

- Construction – The PEA for the proposed project already includes several of the applicable construction mitigation measures, e.g., limit construction equipment idling, use alternative fuels for onsite equipment, etc.

- Miscellaneous – Most of the miscellaneous mitigation measures are not applicable to the proposed, e.g., require best management practices at agricultural and animal operations, or are too vague to provide useful mitigation, e.g., implement an innovative strategy for GHG mitigation, or its efficacy has not been fully verified, carbon sequestration.

In addition to the above discussion of GHG mitigation measures, it is necessary to point out that the analysis of potential adverse environmental impacts incorporates a "worst-case" approach. This entails the premise that whenever the analysis requires that assumptions be made, those assumptions that result in the greatest adverse impacts are typically chosen. This method likely overestimates the actual environmental impacts from the proposed project. Further, the SOx RECLAIM program is a cap-and-trade program so that it is not known and cannot be known at this time if affected facility operators will install control equipment generating the greatest or most significant environmental impacts, will install control equipment that generates fewer or less significant environmental impacts, or purchase SOx RTCs. Consequently, it is speculative at this time to predict with certainty the actual future GHG impacts from the proposed project. As a result, the need for additional GHG mitigation measures will be evaluated on a facility-by-facility basis during the permit application process.

[8] McHale, M. R., McPherson, E. G., and Burke, I. C. 2007. The Potential of Urban Tree Plantings to be Cost Effective in Carbon Credit Markets. Urban Forestry & Urban Greening 6 (2007) 49 – 60.

Finally, because GHG impacts would occur at industrial facilities, AB 32 is mentioned in the Draft PEA as part of the mitigation measure discussion because it is an ongoing process under development by CARB. While there is nothing in CARB's adopted "early action measures" or CARB's GHG reduction measures that specifically apply to the proposed project at this time, as of this writing, CARB has not yet adopted its GHG reduction cap and trade program. When adopted, it is expected to apply to projects that will need to receive permits, including any projects that may occur as a result of amending the SOx RECLAIM program. The purpose of the discussion of AB 32 is to indicate that there are no additional feasible GHG reduction measures that the SCAQMD could adopt that could mitigate impacts from the proposed project and that would be able to go beyond AB 32 requirements. In addition, under U.S. EPA's Tailoring Rule, new or modified facilities that meet or exceed the thresholds will be required to implement BACT for GHGs. With regard to the adequacy of the GHG mitigation measures, GHG-1 and GHG-2, see Responses to Comments 3-39 and 3-40.

2-15 There is no evidence for the potential of NaOH slip from a WGS. The application of the Rule 1401 screening emission level would be justified if there were any indication of NaOH emissions. In fact, with the exhaust stream entering a WGS, the NaOH would effectively disassociate to sodium and hydroxide ions, not remain as NaOH. On this basis, there is no reason to believe that here would be NaOH slip into the atmosphere.

Regarding the commenter's claim that there will be an impact due to pressure drop, refer to Response to Comment 2-25. It is important to note that both sets of consultants in their final reports included contingencies to address equipment-specific, unforeseen circumstances such as pressure drop.

2-16 Evaluation of the SOx RECLAIM inventory indicates that the amount of unused RTCs in the SOx RECLAIM market in 2005 was 1.73 tons per day and by 2008 the amount of unused RTCs in the SOx RECLAIM market had risen to 2.55 tons per day, which would be available for use by the affected facilities. In addition, the proposed amendments include several safety valves to prevent potential facility shutdowns: 1) gradual annual reductions with extended compliance schedule (from 2012 to 2019); 2) monitoring of RTC price trend over a 12-month rolling average; 3) hold public hearing if RTC price exceeds $50,000 per ton (discrete price); and 4) ability for the Governing Board to set aside (give back) up to 100 percent of RTC reductions for any year when RTC price exceeds $50,000 per ton.

Further, the cost-effectiveness of the glass plant complying with the proposed project is estimated to be $9,000 per ton of SOx reduced. The average annual cost for Owens-Brockway to comply with the proposed project is estimated to be $0.52 million (socioeconomic report). Moreover, as discussed in Response to Comment 2-4, Owens-Brockway may be able to comply with the proposed RTC shave with its current control equipment. For these reasons plus the fact that in 2009 Owens-Brockway had net sales of $7.1 billion (see Response to Comment 2-2), Owens-Brockway is not expected to shutdown their operations due to the requirements of the proposed amendments. See also Response to Comment 2-26.

2-17 The commenter implies that the noise impacts from installing a WGS at the Ball-Foster facility in El Monte should be applicable to the Owens-Brockway facility located in Vernon. Further, the commenter asserts that installing a wet gas scrubber, "…resulted in a

significant increase in noise complaints from residents and other businesses." The comparison with regard to residences is not applicable to the Owens-Brockway facility because the Ball-Foster facility is located adjacent to residences while the Owens-Brockway facility is located in an industrial area approximately ¼-mile away from the nearest residences, which is consistent with Vernon's Noise Element Policy, N-2.3: Prohibit the establishment of any new noise-sensitive land uses in Vernon, including but not limited to residences, schools, day-care facilities, and community facilities.

Vernon's Noise Element Policy states, "…In general, industrial noise within the City is not considered excessive because Vernon is a predominantly industrial city with few noise-sensitive properties." The Owens-Brockway facility currently operates scrubbers and has not received reports of any noise problems or complaints from neighboring industrial/commercial facilities. The conclusions in the NOP/IS for noise impacts were based on the potential replacement of two existing dry gas scrubbers with two new WGSs at the Owens-Brockway facility. Since the noise from the existing scrubbers would be replaced with equipment rated at a similar noise profile, any change in the noise level is expected to be minimal relative to the current noise baseline of the facility. A previous installation of WGS technology within the district was rated about 85 decibels (dBA)[9].

When a distance is doubled from a point source, the sound level decreases by six dBA[10]. By applying an estimated six dBA reduction for every doubling distance, for a WGS sound level of 85 dBA at 50 feet, the sound level will be 79 dBA at 100 feet, 73 dBA at 200 feet, 67 dBA at 400 feet, 61 dBA at 800 feet, and 55 dBA at 1,600 feet. As a point of comparison, according to the City of Vernon's Noise Element background noise levels in residential areas are generally within the range of 60 dBA to 70 dBA, however, noise levels can be as high as 85 dBA near the Burlington Northern Santa Fe Railroad tracks to the northeast of the Owens-Brockway facility (See Figure N-4, City of Vernon Noise Element[11]). It is important to note that there are no residences within ¼-mile (i.e., 1,320 feet) of the Owens-Brockway facility as the nearest residence is located at approximately 1,420 feet of the facility. Similarly, it is not reasonably foreseeable that the replacement of two dry gas scrubbers with two wet gas scrubbers with similar noise profiles at the Owens-Brockway facility would create an increase in noise that would be discernable from the existing background noise in the area.

2-18 Regarding the adequacy of water supplies for the proposed project and specific to water supplies in the City of Vernon, see Response to Comment 3-29.

2-19 Regarding the feasibility of mitigation measures, HWQ-1 and HWQ-2, and the cumulative water demand analysis in the Draft PEA, see Response to Comment 2-6.

2-20 When the consultants conducted a site visit of the glass plant, analyzed potential BARCT for the facility, and identified the potential environmental impacts that may occur as a result of installing BACT, the consultants also provided a copy of the report for Owens-Brockway

[9] Final Environmental Impact Report for: ConocoPhillips Los Angeles RefineryPM10 and NOx Reduction Projects: http://www.aqmd.gov/ceqa/documents/2007/nonaqmd/cp/cp_feir.html.

personnel for review and comment. During that process, the Owens-Brockway representatives did not provide any indication that there would be a new and different wastewater stream resulting from the new WGSs. Further, when SCAQMD staff surveyed the Owens-Brockway facility regarding their water and wastewater streams, facility operators did not provide a copy of the requested wastewater permit. The commenter, in raising the issue now, has not provided any substantiating evidence to support the claim that there would be a new wastewater stream. SCAQMD staff has limited information on Owens-Brockway's current wastewater setting and permit specifications because this information was not provided by the operators. Consequently, SCAQMD staff used a surrogate analysis based on the available wastewater data on an existing WGS installation in the District. Further, based on the potential increase in wastewater that may occur at the Owens-Brockway facility, SCAQMD staff does not believe that if WGSs are installed at the glass melting plant that there will be a need to revise the wastewater permit because facilities typically operate at less than maximum capacity to ensure no violations. Further, the commenter did not provide additional information demonstrating that the anticipated increase in wastewater stream as a result of installing a WGS would require modifications to any existing wastewater limitations. Therefore, based on the available information, the comment does not provide evidence refuting SCAQMD staff's conclusion that wastewater impacts from the proposed project would require modifications to existing waster limitations or otherwise create significant adverse wastewater impacts. See also Response to Comment 2-21.

2-21 The proposed project for Owens-Brockway, as confirmed by both sets of consultants, requires the decommissioning of the two existing dry gas scrubbers and the installation of two new wet gas scrubbers (WGSs) downstream from (after) the existing ESPs. The selenium that is added to the glass manufacturing process is in the vapor phase as it exits the furnaces and enters and exits the ESPs as selenium oxide (SeO_2) due to the high temperature. Any gaseous phase selenium that is currently exiting the ESPs is being discharged into the atmosphere. At the very minimum, the WGSs installed after the ESPs will cool the gaseous phase selenium oxide into a solid state, which could then be scrubbed out of the flue gas to be retained in the scrubber effluent solution, and thus, preventing the selenium compound from being discharged into the ambient air. ETS provided several different options for the facility to consider for treatment of the WGS waste stream. Options 1 through 3 involve processing the liquid blowdown from the scrubbers and reintroducing the solids into the process before the ESPs. In particular, Option 3 will not introduce excessive particulate loading to the ESPs since Trona will no longer be utilized as a result of the removal of the dry gas scrubbers from the process (also refer to Response to Comment 2-30). ETS believed that the budgetary allotment was sufficient to address these waste stream considerations. The District recognizes that there are engineering design challenges (e.g., waste stream handling, pressure drop, plugging, et cetera) associated with the installation and operation of WGS technology, but these challenges are not insurmountable within the budgetary framework of the consultants' recommendations.

2-22 This comment is a summary of some of the main points made in subsequent comments in this letter. Therefore, for specific responses to each point refer to Responses to Comments 2-23 through 2-30.

2-23 See Response to Comment 2-2.

2-24 See Responses to Comments 2-3 and 2-4.

2-25 Two sets of consultants, ETS and NEC, visited the Owens-Brockway facility, collected data, interviewed facility representatives and then independently ascertained that WGSs are technically and economically feasible for this facility's furnaces. Both ETS and NEC have direct experience in DGS and WGS technologies, as well as ESPs, as applied to furnace operations at Owens-Brockway facility. SCAQMD staff sent Owens-Brockway's comment letter and SCAQMD staff responses to the consultants for their input, and their input is incorporated into this response[12].

The consultant's (ETS) analysis of the Owens-Brockway facility was finalized in December 2008, nearly two years ago. During this time, representatives from Owens-Brockway rarely participated in the SOx RECLAIM Working Group meetings or provided SCAQMD staff with any questions or feedback on the consultant's report. Only recently, SCAQMD staff received two comment letters from Owens-Brockway submitted on September 22, 2010, and on October 1, 2010. The letters contain several incorrect assumptions and technical errors relative to ETS's analysis as follows:

- The commenter incorrectly assumes that the proposed BARCT configuration relies on the continued operation of the two existing dry gas scrubbers. In actuality, ETS proposed to remove the two dry gas scrubbers upstream of the ESPs and replace them with two new WGSs downstream of the ESPs.
- The current configuration at Owens-Brockway requires redundancy for controlling particulate emissions (via the ESPs) but not for controlling SOx emissions. Owens-Brockway currently operates two dry gas scrubbers with three ESPs connected by piping/valves, but only two ESPs are in operation at any one time while one ESP remains in stand-by mode. ETS recommended removing the two dry gas scrubbers and discontinuing the use of Trona, a very fine powder, in the two dry gas scrubbers. Doing so would be expected to reduce the particulate loading and Trona entrainment to the ESPs. Further, ETS's recommendation may substantially improve the reliability of the two on-line ESPs to the extent that the stand-by ESP may no longer be needed.
- Additional pressure drop is a concern for ALG since ALG incorrectly assumed that the BARCT control configuration recommended by ETS included both the continued operation of the two existing dry gas scrubbers and the installation and operation of two new wet gas scrubbers. Under ALG's incorrect assumption, the configuration of two dry gas scrubbers with two wet gas scrubbers would cause an additional pressure drop across the wet gas scrubbers. However, ETS recommended the removal of the two existing dry gas scrubbers upstream of the ESPs, and their replacement with two new wet gas scrubbers downstream of the ESPs so that there would be no substantial increase in pressure drop. In addition, in ETS analysis, ETS had included the costs for a system fan in the vendor's budgetary quote:

  "Each system comes complete with all necessary pumps, reagent storage tanks, ***system fan*** [emphasis added]*, and stack."*

[12] SCAQMD staff sent Owens-Brockway comment letter and SCAQMD staff's responses to the consultants for review, and received confirmation back that they were in agreement with SCAQMD staff's assessment. The consultants' feedback is included in this response. Emails from James Norton of NEC to Minh Pham on October 12, 2010, and Marshall Bell of NEXIDEA to Minh Pham on October 12, 2010.

ETS made a determination, based on their extensive knowledge and experiences with ESPs, wet gas scrubbers, and dry gas scrubbers, that the pressure drop would not be a concern in this situation. An additional fan or blower to push or pull the flue gas through the WGS would not make the control system recommended by ETS cost-ineffective, because these costs are already included in the estimates.

- The three ESPs (two in operation and one in stand-by mode) were designed to ensure that if one ESP experiences operational difficulties, the stand-by ESP will take its place. ETS recommended removing the dry gas scrubbers and eliminating Trona injection. Based on this recommendation, particulate loading to the two ESPs is expected to be reduced substantially and will improve the reliability of the ESPs. ETS recommended that Owens-Brockway keep one stand-by ESP to handle upset conditions, and thus maintain the integrity of the two wet gas scrubbers downstream of the ESPs. ETS's analysis did not determine that redundancy for SOx control by adding a third scrubber would be necessary because monitoring the pH level and increasing the use of caustic may work efficiently to remove enough SOx.
- As explained above, only two WGSs would be needed. Two consultants, ETS and NEC, both identified suitable, separate locations for placement of the WGSs, Owens-Brockway is not expected to have site limitations associated with the placement of two WGSs within their facility[13].
- The commenter failed to specifically identify the foreseeable additional costs that the consultants might not have included in their analyses. ETS estimated a cost effectiveness of about $5,000 per ton SOx reduced and both ETS and NEC concurred that WGS technology is cost-effective.
- Owens-Brockway did not release any information to ETS at the site visit that could lead to a reasonably foreseeable situation that the wastewater discharge would fail the discharge limit because of selenium. Technology for treating selenium is available. The facility can treat selenium on site or can send the additional wastewater stream (10 gallons per minute) to be treated by LACSD/City of Vernon. Note that ETS budgeted $225,000 to cover the cost of wastewater treatment and this cost is included in the cost-effective calculation. ETS also provides four options to treat the wastewater stream as follows:
    1. The liquid blowdown from the scrubbers could be sent to a storage tank and recycled back to the furnaces for the batch wetting process.
    2. The blowdown could be sent to a storage tank and then to an energy efficient dryer for liquid evaporation. The solid waste could then be placed in a hopper and recycled back to the furnaces.
    3. The blowdown could be sent to a storage tank and then sprayed into the duct ahead of the precipitators to evaporate the water and collect the dry particulate in the ESPs.
    4. The blowdown could be sent to a storage tank and ran through a small skid-mounted filtration system (approximately 6 feet by 6 feet) prior to discharging to the local sanitary sewer system. See also response to 2-30.

[13] SO_x RECLAIM Study Final Report, Module 3-D: Wet/Dry Scrubbing Technology For Container Glass Manufacturing Plant, December 16, 2008, page 2.

- One WGS for a FCCU has been installed and is currently operating at a refinery in the District. The exhaust gas stream from this existing WGS is expected to have similar characteristics (i.e., lower temperature, reduced plume buoyancy, caustic mist) as the proposed WGSs for Owens-Brockway. The WGS at the aforementioned refinery was evaluated to assure that it complies with all state and federal ambient air quality standards and a Permit to Operate was issued by the SCAQMD. If applications for the proposed WGSs are submitted by Owens-Brockway, the WGSs scrubbers will undergo an equivalent or similar evaluation. Moreover, with the exhaust stream entering a WGS, the NaOH would effectively disassociate to sodium and hydroxide ions, not remain as NaOH. On this basis, there is no reason to believe that here would be NaOH slip into the atmosphere.

2-26 Owens-Brockway currently holds 0.31 ton per day of RTCs and the remaining RTCs would be 0.14 ton per day after the proposed 55 percent shave. Owens-Brockway's SOx emissions in 2005 were approximately 0.2 ton per day. Owens-Brockway indicated that the control efficiency of their dry gas scrubbers was demonstrated at 90 percent, but that they are operated at 75 percent to 80 percent. If Owens-Brockway can operate their dry gas scrubbers at 90 percent, then the facility will be in compliance with the 55 percent shave since their emissions at 90 percent control would be 0.1 ton per day, below the 0.14 ton per day allocation after the shave. Under this scenario, Owens-Brockway will have surplus credits of 0.04 ton per day, which can be made available in the open market and could generate a substantial revenue stream to the company. This revenue stream could be even larger if Owens-Brockway elects to install higher efficiency WGSs.

However, if Owens-Brockway elects not to operate their dry gas scrubbers at 90 percent control, then the facility operators can purchase 0.06 ton per day (0.2 ton per day 2005 baseline – 0.14 ton per day = 0.06 ton per day) to be in compliance with 55 percent shave. The RTCs can be purchased from investors or from other SOx RECLAIM facilities that have surplus RTCs. The surplus pool has approximately 1.73 tons per day of unused RTCs in 2005, and 2.55 tons per day of unused RTCs in 2008. For these reasons, SCAQMD staff did not assume that Owens-Brockway would shut down their facility because of the proposed 55 percent shave for SOx RECLAIM.

For the above reasons, and the fact that the annual cost of compliance is estimated to be $0.52 million (Socioeconomic Report) for a facility whose parent company had net sales of $7.1 billion[14] in 2009 and a gross profit margin of 21 percent (see Response to Comment 2-2), SCAQMD staff concluded that it was not reasonably foreseeable that Owens-Brockway would shut down its facility because of the proposed 55 percent shave for SOx RECLAIM. Consequently, environmental impacts such as those mentioned in the comment are also not reasonably foreseeable, so further analysis is not required.

2-27 BARCT technology is improving over time. For example, dry gas scrubbers operating at 80 percent control efficiency were considered as BARCT in 1994. Current control technologies routinely demonstrate 95+ percent control efficiencies and can achieve control levels of 5 ppmv or better. Owens-Brockway can achieve these reductions cost-effectively.

[14] O-I Announces Third Quarter Earnings Conference Calland Webcast, September 20, 2010. http://www.o-i.com/nth_us.aspx?id=400; http://www.o-i.com/about_oi.aspx?id=1348 and http://www.o-i.com/nth_us.aspx?id=400

Therefore, Owens-Brockway should not be included in the list of exempt facilities in Table 5 of the PAR 2002.

2-28 SCAQMD staff and the consultants[15] disagree with ALG's technical assessment in a number of areas as explained in the following paragraphs.

- As explained in Response to Comment 2-25, the assumed configuration of the proposed BARCT to include dry gas scrubbers is incorrect. The combination of monitoring pH levels, using a sufficient amount of caustic solvent for controlling SOx emissions, and having ESPs located upstream for controlling particulate emissions would prevent excessive particulate loading and catastrophic failure to the WGSs located downstream of the ESPs.

- Since three WGSs are not required for redundancy as each can be sized to handle the entire flue gas flow from the ESPs, plot space limitations are not expected. Both consultants visited the site, evaluated the situation, and concurred that there is available plot space to located two new WGSs.

- Operational problems are site- and equipment-specific, particularly in cases where process changes are made upstream of existing systems such as in the case of the Ball-Foster facility experiencing excessive loading of particulate emissions to their venturi scrubber converting their furnace to an oxy-fuel furnace. The venturi scrubber should be redesigned to handle a lower flow with higher particulate loading from the oxy-fuel furnace. As any new equipment would need to be designed for a specific installation, the design would need to take into account all operating modes and upstream conditions. Therefore, SCAQMD staff finds that the problems occurring at the Ball-Foster facility were due to the re-use of existing control equipment instead of redesigning the controls, and these problems would not be expected to apply to the Owens-Brockway facility. In addition, Owens-Brockway has three ESPs located upstream of the scrubbers to control particulate matter which will help prevent excessive buildup of particulate emissions in the WGSs.

- Dry gas scrubbers operating at 80 percent control efficiency are no longer considered BARCT because current state-of-the-art systems can reliably achieve 95 percent or more SOx reductions and achieve SOx emission levels of 5 ppmv or lower. SCAQMD staff, therefore, recommends the BARCT level for glass melting furnaces to be 5 ppmv. However, if the dry scrubbers are operated at 90 percent efficiency, then Owens-Brockway should be able to comply with the proposed RTC shave.

2-29 Regarding the suggestion to clarify the language in subparagraph (f)(1)(Q) of Rule 2002, SCAQMD staff disagrees with the commenter's proposed interpretation. The intent of this subparagraph is that any facility entering the RECLAIM program after the date of adoption and that operates the basic equipment in Table 4 shall have its SOx allocations determined according to the BARCT level listed in Table 4 or the permitted emission limits, whichever

[15] SCAQMD staff sent Owens-Brockway comment letter and staff's responses to the consultants for review, and received confirmation back that they were in agreement with staff's assessment. The consultants' feedback is included in this response. E-mails from James Norton of NEC to Minh Pham on October 12, 2010, and Marshall Bell of NEXIDEA to Minh Pham on October 12, 2010.

is lower. Existing facilities that operate the basic equipment listed in Table 4 will have their allocations adjusted in accordance with Rule 2002, subparagraphs (f)(1)(I) and (f)(1)(J) at the Table 4 BARCT levels, effective 2012. It should be noted that all Table 4 equipment in existing non-RECLAIM facilities have achieved the proposed BARCT standards (e.g., diesel combustion). This clarification will be made in the proposed amended rule and Staff Report.

2-30 SCAQMD staff's responses to the individual comments are summarized as follows, but because of overlapping concepts in several bulleted items, the order of the responses does not necessarily directly correspond to the order of each bulleted item in the comment letter:

- The 2005 reported emissions for Owens-Brockway's glass furnaces were approximately 0.2 ton per day with their dry gas scrubbers typically operating in the range of 75 percent to 85 percent control efficiency, but occasionally achieving a control efficiency as high as 90 percent. The background on Owens-Brockway's furnaces and control equipment provided in the comment is consistent with this 2005 emissions data and the information documented by ETS (i.e., testing on the dry gas scrubbers demonstrated up to 90 percent control efficiency). If the dry gas scrubbers were operated consistently at a 90 percent control efficiency level, then Owens-Brockway would emit approximately 0.1 ton per day and as such, would be in compliance with the proposed 55 percent shave without additional control.

- SCAQMD staff knows of no installation in which a facility relies upon using dry gas scrubbers, dry ESPs, followed by wet gas scrubbers to achieve the emission reductions recommended by the consultants. However, based on the consultants' reports, SCAQMD staff believes that the level of 5 ppmv SOx (which represents a 95 percent control efficiency or more) can be achieved in practice, is cost-effective and is not expected to create the severe problems alleged by the commenter's technical assessment.

  The proposed BARCT level for glass melting furnaces has been achieved in practice. Specifically, the Puget Sound Clean Air Agency in Seattle, Washington, provided SCAQMD staff with source test and CEMS data that demonstrates compliance with 5 ppmv SOx levels at 96 percent control efficiency via Tri-Mer's Cloud Chamber scrubber for a furnace with a permit limit of 1.6 pound of SOx per ton of glass pulled but tested at 0.0062 pounds of SOx per ton of glass pulled[16, 17]. SCAQMD staff was provided with supporting documentation from Tri-Mer and other WGS vendors that demonstrated that the Cloud Chamber scrubber as well a packed bed scrubber, venturi scrubber, or open throat type of scrubber can be used to achieve 5 ppmv SOx level when appropriately designed and operated.

  There are several types of WGSs that can be considered for the Owens-Brockway facility: 1) quench, vertical packed bed scrubbers as recommended by Manufacturer A; 2) simple open-throat scrubbers as recommended by Manufacturer D; or, 3) fluidized rotating scrubber as offered by Manufacturer B. NEC recommended

[16] Horizon Engineering, "Source Test Evaluation Report for Saint-Gobain, Seattle, Washington, Glass Melting Furnace No. 5 with Cloud Chamber Scrubber," September 18, 2009.

[17] CEMS Summary Report from Saint-Gobain to Puget Sound Clean Air Agency, for a period from October 1, 2009 to October 31, 2009.

Manufacturer D's open-throat type and ETS recommended Manufacturer A's packed bed scrubber. Manufacturer A indicated that the packed bed scrubber can tolerate up to 20 micrograms per cubic nanometer (µg/nm3) of insoluble particulate without clogging; and if the particulate is soluble (e.g., sodium sulfate), then the packed bed scrubber would not have a problem with plugging[18]. The SOx RECLAIM program does not require Owens-Brockway's operators to install any particular type of scrubber. In fact, Owens-Brockway's operators are encouraged to study their options further and research the type of WGSs and solvents that best fits their operation and emission profiles.

- The control configuration recommended by ETS (which was proposed by Manufacturer A) consists of three existing ESPs followed by two new WGSs. Manufacturer A and ETS recommended the removal and replacement of the two existing dry gas scrubbers with two WGSs downstream of the three existing ESPs. Further, the commenter incorrectly assumes that three WGSs would be needed to correspond with the three ESPs units. Even though the three ESPs are connected by piping/valves, only two are in operation at any one time and the one remains in standby mode. Thus, there is no need to install three WGSs when there are only two operational ESPs at any one time. For these reasons, ETS recommended replacing the two existing dry gas scrubbers with two new WGSs. Further, because the analysis is based on the replacement of the two existing dry gas scrubbers with two new WGSs, and not three WGSs as suggested by the commenter, the cost-effectiveness analysis only includes the costs associated with the installation and operation of two new WGSs downstream of two existing ESPs. Also, because ETS recommended the removal of the two existing dry gas scrubbers, the cost-effectiveness analysis does not and should not be based on the continued operation of the dry gas scrubbers in addition to the two WGSs.
- Regarding the sizing of the two WGSs, since each of Owens-Brockway's ESPs operates at a capacity of 30,000 acfm, or at combined capacity of 60,000 acfm with one ESP in stand-by mode, then the combined capacity of the two WGSs would also need to be sized at 60,000 acfm, not 90,000 acfm as suggested by the commenter. However, Owens-Brockway operators may choose to build a larger system for redundancy (e.g. 90,000 acfm instead of 60,000 acfm). A larger system will cost more but it will not make the BARCT recommended by the consultants become cost-ineffective (i.e. larger than $50,000 per ton) since the cost-effectiveness for the 60,000 cfm system was estimated to be $5,000 per ton, and the capital costs are proportional to the $(90{,}000/60{,}000)^{\exp 0.6} = 1.28$ factor.
- As explained in Response to Comment 2-25, additional pressure drop was a concern for ALG since ALG incorrectly assumed that the BARCT control configuration recommended by ETS included both the two dry gas scrubbers and the two wet gas scrubbers. However, ETS recommended the removal of two dry gas scrubbers upstream of the ESPs, and replace those with two WGSs downstream of the ESPs. Also, Manufacturer A included a fan in their proposal. Therefore, the manner in which the equipment could be configured should remedy any concerns of pressure drop across the system.

[18] Email from Manufacturer A to Minh Pham – Solution Based Absorbents for Scrubbers, January 29, 2010.

- The commenter incorrectly assumes that Trona will still be needed even though ETS recommended stopping the use of Trona and replacing the two existing dry gas scrubbers upstream of the ESPs with two new WGSs downstream of the ESPs. Removing the dry gas scrubbers and eliminating the use of Trona would substantially reduce the particulate loading to the ESPs. Further, as is the case with current operations at Owens-Brockway, if an ESP goes offline, the stand-by ESP would become operational so that only two ESPs would be operational at any time. Thus, there would be no extra loading to the WGSs in the event an ESP goes off-line. Overall, this configuration would reduce the loading to the WGSs downstream of the ESPs.

- The suggestion that the WGS proposed by ETS is under-sized because the particulate loading allowed by the permit (0.08 grains/dry standard cubic feet) is an order of magnitude higher than the amount assumed by ETS (0.008 grains/dry standard cubic feet) represents a misunderstanding about what data is considered when sizing a WGS. The capacity or size of a WGS is dependent upon several factors. ETS provided the vendors with flue gas flow rates, inlet concentrations, and other necessary parameters so that the manufacturers could estimate the size and associated costs of the WGS. Because flue gas flow rate, not particulate loading, is the critical parameter that was used to determine the equipment costs and the size of the WGS, the WGS recommended by ETS would be able to handle the permitted particulate loading (0.08 grains/dry standard cubic feet).

- Owens-Brockway reported that the facility is currently sending wastewater to the LACSD and the City of Vernon to be treated at a rate of 41.89 million gallons per year which equates to approximately 80 gallons per minute (gpm). Owens-Brockway has a maximum discharge limit of 131.4 million gallons per year or 250 gpm. The increase in discharge due to the two WGSs is 10 gpm which is expected to mainly contain soluble sodium sulfate that would result from using caustic solvent as the scrubbing agent. With an additional discharge of 10 gpm, Owens-Brockway is far below their permitted threshold of 250 gpm. In addition, on October 26, 2010, following SCAQMD staff's request, Owens-Brockway provided SCAQMD staff with their facility's industrial wastewater discharge permit issued by the LACSD which shows that currently LACSD has effluent concentration limits for arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, zinc, cyanide, and total dissolved sulfides. There is no effluent discharge concentration limit for selenium on Owens-Brockway's industrial discharge permit. Furthermore, SCAQMD staff estimated the concentration of selenium that could potentially be present in Owens-Brockway's wastewater stream based on their annual emission reports from 2002 to 2009. Selenium concentrations in their wastewater stream was estimated to be around 0.022 mg/L[19], much less than the thresholds set in the Code of Federal Regulations(CFR), Part 268 – Land Disposal Restrictions for wastewater and non-wastewater. For these reasons, SCAQMD staff believes that both the LACSD and the City of Vernon will be able to receive and treat an additional 10 gpm waste stream that contains trace amounts of selenium and other inorganic compounds.

  The consultant (ETS) also allocated $225,000 into the scrubber equipment cost estimate for handling the waste stream from the scrubbers (e.g., selenium). The $225,000 estimate was based on information provided by Manufacturer D which has

[19] Email from Kevin Orellana to Minh Pham on October 26, 2010.

expert knowledge of WGS technology and WGS effluent waste treatment. The estimate was also based on relevant experience with the waste stream from a glass manufacturing facility located in Seattle, Washington[20]. In addition, ETS, in their final report, provided four options for Owens-Brockway to treat the waste stream onsite:

1. The liquid blowdown from the scrubbers could be sent to a storage tank and recycled back to the furnaces for the batch wetting process.
2. The blowdown could be sent to a storage tank and then to an energy efficient dryer for liquid evaporation. The solid waste could then be placed in a hopper and recycled back to the furnaces.
3. The blowdown could be sent to a storage tank and then sprayed into the duct ahead of the precipitators to evaporate the water and collect the dry particulate in the ESPs.
4. The blowdown could be sent to a storage tank and ran through a small skid-mounted filtration system (approximately 6 feet by 6 feet) prior to discharging to the local sanitary sewer system.

Lastly, since technology for selenium treatment is available, SCAQMD staff recommends that Owens-Brockway operators conduct their own evaluation of these recommended options to find an appropriate method to treat any selenium in the WGS wastewater. There are no significant environmental impacts expected with the options quoted above. While the commenter criticized Option 3 (the comments were based on the incorrect assumption about the continued use of dry gas scrubbers and Trona injection), no comments were submitted relative to Options 1, 2 and 4.

- Regarding the comment about moisture build-up/clogging in the ESPs, see Responses to Comments 2-3 and 2-28.
- There are hundreds of scrubbers operating across the nation that currently utilize caustic solution (NaOH, 50 percent by weight) as a scrubbing agent. The commenter has failed to provide evidence to support the claim that the use of caustic solution will create additional environmental impacts, other than what was already identified and analyzed in the Draft PEA. Further, as mentioned in Response to Comment 2-15, there is no evidence for the potential of NaOH slip from a WGS. The application of the Rule 1401 screening emission level would be justified if there were any indication of NaOH emissions. In fact, with the exhaust stream entering a WGS, the NaOH would effectively disassociate to sodium and hydroxide ions, not remain as NaOH. Thus, there is no reason to believe that the use of caustic in a WGS would emit NaOH slip into the atmosphere.
- Regarding compliance with the new federal NO2 standard, see Response to Comment 2-13.
- The commenter refers to the Green Chemistry Initiative and suggests that the use of NaOH may be inconsistent with its requirements. The "Green Chemistry Draft Regulation for Safer Consumer Products[21]" is a draft regulation prepared by

[20] Email from ETS, Inc. to Minh Pham on October 27, 2010.
[21] http://www.dtsc.ca.gov/PollutionPrevention/GreenChemistryInitiative/upload/Safer-Product-Alternative-Regulations-6-23-10.pdf

California Department of Toxic Substances Control (DTSC) that specifies the processes for DTSC to scientifically and systematically identify and prioritize chemicals and consumer products, for manufacturers to conduct alternatives assessments, and for DTSC to impose regulatory responses for alternatives selected by manufacturers.

According to the draft regulation, the term "Green Chemistry Principles" means: 1) prevention of waste rather than treating it or cleaning it up; 2) incorporation of all materials used in the manufacturing process in the final product; 3) use of synthetic methods that generate substances with little or no toxicity to people or the environment; 4) design of chemical products to be effective, but reduce toxicity; 5) phase-out of solvents and auxiliary substances when possible; 6) use of energy efficient processes, at ambient temperature and pressure, to reduce costs and environmental impacts; 7) use of renewable raw materials for feedstocks; 8) reuse of chemical intermediates and blocking agents to reduce or eliminate waste; 9) selection of catalysts that carry out a single reaction many times instead of less efficient reagents; 10) use of chemicals that readily break down into innocuous substances in the environment; 11) development of better analytical techniques for real-time monitoring to reduce hazardous substances; and, 12) use of chemicals with low risk for accidents, explosions and fires.

While NaOH, a toxic air contaminant (TAC) that is a non-cancerous but acutely hazardous substance, is a very common scrubbing agent, it is not the only solvent that can be used in Manufacturer A's scrubber. However, for a worst-case analysis in the Draft PEA, the use of NaOH was assumed. Thus, if Owens-Brockway operators choose to install WGSs and apply the draft Green Chemistry Principles to their choice of solvent for the WGSs, soda ash, a non-toxic, non-cancerous, and non-hazardous substance, could be utilized instead as an alternative scrubbing agent.

- While there may not be sufficient space for three WGSs, only two scrubbers were recommended by the consultants (ETS and NEC) with input from Owens-Brockway's operators as explained in Response to Comment 2-25. Both ETC and NEC were in agreement that three WGSs are not needed to handle the entire flue gas flow (60,000 acfm) from the two ESPs and that the facility had sufficient space for siting two WGSs. Thus, there is no need to find space for a third WGS.
- Regarding the comment relative to siting the control equipment, the consultants identified two different potential locations at the site for the WGSs. While the specifics of the potential locations are confidential at the request of the facility operators and cannot be disclosed in this response, the confidential details have been provided to Owens-Brockway personnel. What can be disclosed in this document, however, is ETS's general description of the plot space availability at the Owens-Brockway facility:

  > *"The plant has limited space available for additional equipment, approximately a 14' x 20' footprint between two existing scrubbers. In addition O-I personnel indicated that the height of any new equipment could not exceed 30 feet above the top of the existing scrubbing vessels. A request was made of O-I to provide us with dimensional information pertaining to available space for the Manufacturer A equipment footprint.* ***They stated that there is space available*** [emphasis added]. *Horizontal distance is 63' depending on the location of the ducting out of the pieces*

> *of equipment. This does not take into account the vertical distance which will depend on location of entry to the stream*[22]*."*

In addition, NEC's general description of the plot space availability is as follows:

> *"We located an elevated area just to the west of the ESP's* [sic] *and adjacent to the existing ammonia storage tank where Facility D felt the unit could potentially be located. This new area is located above an existing truck turnaround area*[23]*."*

Neither ETC's nor NEC's reports reflect any suggestions from Owens-Brockway's representatives that the WGSs would need to be sited in a parking lot or that an existing structure would need to be torn down. In the context of the comment, it seems that the commenter is suggesting these circumstances based on the misunderstanding that a third WGS would need to be installed. SCAQMD staff continues to assert that two WGSs sufficiently sized can provide the necessary capacity to ensure compliance with the proposed BARCT for glass melting furnaces. See also Responses to Comments 2-25 and 2-28.

For these reasons, SCAQMD staff continues to believe that there is sufficient space at the Owens-Brockway facility to site two WGSs. Further, the costs associated with the siting options proposed by the consultants have already been included in the cost-effective and socioeconomic analyses. See also Response to Comment 2-2.

- The ETS analysis included all of necessary costs. However, NEC recommended raising ETS's costs to include contingencies, costs for additional ducting and valves for an alternative location. The commenter indicated that additional costs for CEMS upgrade were also needed. This additional cost would be covered by NEC's recommended cost adjustment for contingencies. By including all of the additional costs suggested by NEC, which would cover the cost for the CEMS upgrade, the BARCT recommended by ETS would remain cost-effective. Even with the adjustments made to ETS's initial cost estimates, NEC concurred that the control costs for WGSs would be cost-effective for glass melting furnaces.
- With regard to the comment about the technical data that was relied upon to support a 25-year useful life of a WGS, a leading manufacturer of WGSs provided the SCAQMD staff with a confidential list of all its wet scrubbing systems installed worldwide. In this list, there were 20 wet gas scrubber installations that are 25 years or older and still operating. For this reason, SCAQMD staff applied a 25-year useful life assumption for WGSs.
- Regarding the implementation challenges face by the Ball-Foster facility, see Response to Comment 2-3.
- Regarding the proposed BARCT level and how it relate to the emissions at glass plant located in Seattle, Washington, see Response to Comment 2-4.

Subject: WSPA Comments on SCAQMD SOx RECLAIM Draft Program Environmental Assessment (DPEA)

Sent on behalf of Catherine Reheis-Boyd.

Dear Ms. Radlein:

Please see attached Western States Petroleum Comments on the SCAQMD SOx RECLAIM Draft Program Environmental Assessment (DPEA). If you have any questions, please call Cathy at (916)498-7752 or email: cathy@wspa.org.
Thank you.

Diamond Bar, CA. 91765-4182

Dear Ms. Radlein:

SCAQMD SOx RECLAIM Draft Program Environmental Assessment (DPEA)

Attached are the Western States Petroleum Association's (WSPA's) comments related to the Draft Program Environmental Assessment (DPEA) for proposed amendments to Regulation XX, the RECLAIM SOx shave. WSPA is a non-profit trade association representing twenty-eight companies that explore for, produce, refine, transport and market petroleum, petroleum products natural gas and other energy products in California and five other western states.

WSPA member companies operate petroleum refineries, distribution terminals and other facilities in the South Coast Air Basin. WSPA has been involved in air quality issues in California and the South Coast for 40 years. We pioneered the use of computerized modeling, and sponsored some of the first regional air quality monitoring programs that documented ambient air quality and the impacts of atmospheric emissions. 3-1

The RECLAIM Work Plan that was initiated in January 2010 identified environmental impacts and substantial cost factors associated with this regulatory proposal. WSPA made a commitment to follow the Work Plan in January 2010. We continue to be responsive and transparent in working with the District staff.

As an outgrowth of the work plan, and in an effort to understand the basis for our differing views concerning the costs and environmental benefits of various reductions in RTC allocations, staff from WSPA and the District have recently begun development of a clear and concise cost summary. That cost summary identifies the policy choices facing industry and the District. 3-2

If this effort is successful, we see development of the summary as an important first step in informing the SCAQMD Board in preparation of the upcoming adoption hearing. We will keep you informed of our collective progress.

As part of our ongoing effort to work with the District and balance environmental impacts with costs, WSPA first proposed a 25% shave. Then, using alternative methodology we presented a 33% shave proposal. WSPA recently increased our proposal to a 40% shave.

The estimated costs to the refining industry for the 40% proposal are still over half a billion dollars. This represents a huge commitment from the refining industry to support the District's efforts to reduce emissions. Despite our proposal the District's position remains unchanged at a 55% shave with an estimated cost to the refining industry of over $1.5 billion.

WSPA's proposal exceeds all applicable local, state, and federal regulatory requirements for this proposed rule making. WSPA believes the District should accept our proposal or bring forth a more realistic and reasonable proposal than the current 55% shave – one that balances the clean air obligations of the District with the economic health of the region and the refining industry.

3-2 Cont'd

Background

As currently proposed, the amendments to Regulation XX rely heavily on the control of industrial facilities including several refinery source categories. WSPA has reviewed all the SCAQMD reports by consultants and District staff, and provided feed back to the District staff.

Detailed comments for the District's 55% proposal are provided in the attachment; however, the DPEA only partially addresses some of the impacts and cost issues. Our attached comments note deficiencies in areas where additional critical analyses should be done. We would like to highlight the following:

3-3

1. RTC Market Analysis

   The DPEA concludes that the current shave proposal will not result in constraints to the RECLAIM market and states: "there will be sufficient SOx RTC's available to maintain trading within the SOx RECLAIM program." This statement has not been substantiated by any analysis conducted as a part of the DPEA or any other document available for review to date.

   The SCAQMD arrived at this conclusion before the socio-economic or market impacts studies have been concluded. District Staff needs to conduct an analysis and make it available to the public for review and comment so that it may inform the Board's decision.

3-4

2. Cost to Comply

   WSPA has repeatedly informed the District that the estimated compliance costs are underestimated substantially. The District's consultants' estimates failed to consider the project scope including, but not limited to space limitations, additional utility infrastructure and the practical limitations placed on working refineries. The depth of the proposed shave will drive compliance costs far beyond any reasonable level and exceeds acceptable cost effectiveness thresholds.

3-5

1415 L Street, Suite 600, Sacramento, California 95814
(916) 498-7752 • Fax: (916) 444-5745 • Cell: (916) 835-0450
cathy@wspa.org • www.wspa.org

WSPA agrees with the conclusion of the District's consultant Norton Engineering that the cost effectiveness analysis needs improvement. The Norton Engineering Report documented various deficiencies in the analysis of five out of six source categories.

The Report encourages the District to re-calculate the cost effectiveness analysis for the affected source categories; however, the District has refused to follow the recommendation of its consultant and recalculate the cost effectiveness.

The District's overly aggressive proposal incorporates the seizure of "unused" RTC's in a manner that doubles the compliance cost. The costs to achieve emission reductions required by the proposed shave are nearly double the costs required to achieve emission reductions equivalent to installation of BARCT controls on refinery sources.

The DPEA should expressly evaluate the costs of achieving BARCT levels of emission reductions. We note that this approach was partially discussed as Alternative C; however, that did not expressly discuss the implications for not confiscating an additional 1.75 TPD in RTC's.

3-5 Cont'd

3. The DPEA concludes the cumulative mitigation measures for water supply and green house gas (GHG) emissions are insufficient to mitigate impacts below the level of significance. This finding requires the District to adopt a statement of over-riding consideration in order to certify the DPEA findings. Because of this fact, it seems appropriate that the District consider an alternative that is less environmentally adverse.

3-6

4. The District's DPEA notes that Alternative C poses fewer environmental impacts and may not require a statement of over-riding consideration for either water or GHG mitigation. The District should specifically address why Alternative C was not selected as this would satisfy all current local, state and federal regulatory requirements.

3-7

5. The District's Norton Report notes that technologies identified as BARCT for cement plants and acid plants are neither typical installations nor appropriate for identification of BARCT. The DPEA should revisit the identification of BARCT and correct errors associated with the Staff Report, and should document the resulting consequent changes in the environmental impacts.

3-8

6. The DPEA is insufficient in scope to support the permitting of required equipment and related processes as companies prepare to meet compliance objectives. Key issues such as New Source Review (NSR), Prevention of Significant Deterioration (PSD) and offsets, are not addressed. Mitigation measures have not been documented sufficiently and the analysis of these impacts may not be sufficient to support applications submitted in support of projects proposed to achieve the required shave levels.

3-9

WSPA is committed to working with the SCAQMD to facilitate a constructive SOx rule making that will result in meeting the necessary environmental objectives at a cost that will not economically damage the region or the refining industry. We have negotiated in good faith, moving from an initial position of a 25% shave to our current 40% shave position, which results in 4.7 TPD of actual reductions.

3-10

1415 L Street, Suite 600, Sacramento, California 95814

cathy@wspa.org • www.wspa.org

Since this DPEA will be used to support permitting and actual project implementation, it is vital that the environmental impacts and mitigation measures adopted are based on an accurate and complete body of evidence.

WSPA supports the 2007 AQMP analysis and related emission reduction targets, but with a BARCT adjustment that is based on a complete and accurate technological and cost effective determination. This in-turn requires a sound environmental impacts analysis, based on realistic compliance assumptions.

3-11

Page A-1

ATTACHMENT A: GENERAL COMMENTS

Overall

Comment: The District should have analyzed environmental impacts of seizing the "unused" RTCs. These are NOT unused, but are necessary for the facilities to ensure compliance with the existing rule and avoid having to purchase RTCs in an adverse market. In addition, a market for RTCs gives facilities flexibility when implementing compliance options and at the end of each cycle. WSPA requests that the District analyze the impact of a highly constrained market on key environmental factors such as air emissions, GHG emissions and water use. 3-12

Comment: The District should have re-calculated the cost-effectiveness for all technologies because of the Norton Report's findings. The District should, in particular, recognize that there were major edits in 5 of the 6 source categories reviewed by Norton Engineering. WSPA requests that the updated cost-effectiveness calculations be included in the Programmatic Environmental Assessment (PEA). This evaluation is critical to understanding the environmental impacts of the proposed project and identified alternatives. 3-13

Comment: The DPEA did not adequately address the possible need for additional water supplies or the costs for and reliability of the supply of the additional water needed. For example, given the current restrictions in the supply of potable water, the DPEA makes reference to the substitution of recycled water.

However, the expanded use of recycled water was not carefully evaluated. For example, costs associated with building the needed infrastructure to the facility, infrastructure within the facility, expansion and operation of the process water treatment plant, cost of the recycled water itself, and cost of waste water handling were not discussed in any detail. Another critical issue not addressed is the reliability of the recycled water source and delivery infrastructure. Refinery process units are 24/7 operations, requiring the same level of dependability from any utility required to operate related emission control equipment.

In order to prepare a complete PEA, the District should expand its analysis of water and wastewater use and handling (see Attachment B, Comments 1-3 and 1-5). 3-14

BARCT Technology

Comment: A comprehensive discussion of De-SOx technology feasibility and control effectiveness – which are highly unit-specific – is necessary. In addition, De-SOx additives have the effect of diluting the circulating cracking catalyst and potentially adversely impacting conversion within the FCCU. Such a reduction of cracking effectiveness would have a significant adverse economic impact on a refinery. 3-15

Comment: No "dry alternative" is considered. The District, in order to evaluate the full range of options, should consider Alternatives that do not include use of a Wet Gas Scrubber. We note, for example, that even Alternative C features use of four scrubbers. 3-16

Comment: The District claims (page 2-6) that there are "three main strategies that can be employed" to reduce SOx emissions from SRU/TGUs - 1) increase the efficiency of the SRU, 2) improve the efficiency of the TGU, and 3) install a wet gas scrubber. WSPA notes that so-called strategies 1 and 2 are not strategies at all but, rather are 3-17

1

general and non-specific objectives. The District goes on (Table 2-2, page 2-10) to suggest that a candidate BARCT technology for SRUs would be the use of a selective oxidation catalyst. Such catalysts, to WSPA's knowledge, have never been used in an SRU and, consequently, cannot be deemed a viable option. Further, if staff is going to consider this technology, the possible impacts to air emissions, energy use and water consumption as well as an updated cost analysis also need to be considered. 3-17 Cont'd

Comment: To consider a WGS for the calciner, the District must recalculate the cost effectiveness with Norton's updated numbers. This recalculation will help inform the decision on the comparative impacts of various control strategies on water, electricity use and air emissions. 3-18

Comment: The District failed to consider the reasonable worst-case scenario of no additional recycled water supplies dedicated to the RECLAIM facilities. As noted in Comment 1-3 and 1-5 in Attachment B, it is quite possible that the facilities will have no access to new supplies or future increases in the supply of recycled water. The current analysis is insufficient for both the "most likely" and "mitigated" scenarios. Thus the conclusions on P 5-83 are unsupported by the analysis. 3-19

Comment: Table 4-1 indicates that a 5 ppm SOx level can be achieved on FCCUs by using De-SOx catalyst. Yet, no underlying data are provided to show this to be the case. If the District is now asserting that 5 PPM SOx level can be achieved by De-SOx catalyst, then this data should be presented as part of the Final PEA because this option may have significant implications on energy use, water use and emissions compared to other alternatives. 3-20

Comment: The District Staff states (pages 2-5 and 6) that their consultant determined that utilizing a wet gas scrubber for process heaters or boilers would not be cost-effective, but that refineries can "opt" to use lower sulfur-containing fuels in order to reduce SOx emissions from these combustion sources. This assertion is inaccurate.

Fuel gas sulfur content can only be reduced to the extent allowed by the capacity of a facility's fuel gas treating system. Further, the refinery's sulfur plant has to have the capacity to process the additional sulfur that would be removed from the fuel gas. A detailed analysis of the effort required to reduce sulfur emission is essential for a complete PEA. WSPA encourages an expanded review of the costs, environmental impacts and resource commitments associated with various sulfur control technologies. 3-21

Comment: The District claims (page 2-13) that the sulfur content of refinery fuel gas may be further reduced to a range between 25 ppmv and 35 ppmv and the outlet SO_x concentrations from refinery boilers and process heaters may also be limited to less than 20 ppmv by implementing "efficiency improvements" to fuel gas treatment systems. However, the District does not provide any data to support this contention or any analysis to support their conclusions.

There is no information provided about cost effectiveness of such "efficiency improvements." Some refineries included fuel gas treatment options in the WSPA cost survey and the District is aware of this. But, any such treatment enhancements are not necessarily applicable or cost effective for every refinery. While not a part of the BARCT adjustment, if the District wishes to include this approach within the PEA, it would seem appropriate to conduct more site-specific analyses. 3-22

BARCT Definition

Comment: The Health and Safety Code specifically defines BARCT as "…best available retrofit technology means an emission limitation that is based on the maximum degree of reduction achievable taking into account environmental, energy and economic impacts by each class or category of source." Because of the significant water demand impacts of the proposed rule, a "dry" technology alternative should be included in the DPEA. Currently, Alternative C contemplates a reduction in the number of categories subject to wet gas scrubber technology. 3-23

Draft Rule and Calculated Emission Reductions

Comment: Regarding paragraphs (f)(1)(N) and (M) of the rule, the $50,000/ton threshold should be based on perpetuity credits, not single year credits, because perpetuity credits are more reflective of long-term compliance costs. The price of single year credits would just depend on whether a facility had excess credits during that particular year due to, for example, a turnaround. 3-24

The single year credit cost is not directly related to the true cost of controls. This aspect of the rule should be addressed as part of the PEA and the Socioeconomic Report that must be prepared to inform the Board in its deliberations.

Draft Rule Emission Reductions

Comment: The emission reductions shown in the table below are still too aggressive, particularly in terms of feasibility concerns and significant environmental impacts. Tonnage in the table is based on the schedule for emission reductions in the Proposed Project. The tonnage and emission reduction schedule should be provided for all Alternatives.

For example, the DPEA should consider the environmental impacts of a less aggressive reduction such as 1 TPD each year for the first 3 years and then 0.4 TPD from 2015 - 2019 for a total of 5 tons by the end of 2019. 3-25

Year	Pounds/yr	Tons/yr	Cumulative Tons/Day	Incremental Yearly Ton/Day Reduction
2012	1,095,000	547.5	1.5	1.5
2013	2,190,000	1095	3	1.5
2014	3,285,000	1642.5	4.5	1.5
2015	3,518,600	1759.3	4.82	0.32
2016	3,752,200	1876.1	5.14	0.32
2017	3,985,800	1992.9	5.46	0.32
2018	4,219,400	2109.7	5.78	0.32
2019 and after	4,453,000	2226.5	6.1	0.32

Page B-1

ATTACHMENT B: MAJOR COMMENTS

EXECUTIVE SUMMARY (CHAPTER 1)

SCAQMD's response to the controversy in the amount of the SOx shave as indicated in Table 11 on page 1-11 of the DPEA is as follows: "…the rule analysis shows that after the shave is imposed, there will be sufficient SOx RTCs available to maintain trading within the SOx RECLAIM program."

> **Comment 1-1**: The District has not provided any analysis in its DPEA to support this statement. This is especially important because the current SOx market is very "thinly traded" with a limited number of participants. Hence it seems important that the District assess the environmental impacts if, as has occurred in other emission trading programs, SOx market trading is distorted or impaired due to the proposed shave and seizure of currently "unused" RTCs.
>
> Moreover, the assertion that there will be sufficient RTCs available to maintain trading within the program after an aggressive shave in RTCs has not been substantiated by fact. In fact, there is no way for the District to predict, with any certainty, future market response to reductions in the RTC market consistent with the proposal, nor has the possibility for significant environmental impacts associated with an aggressive shave in RTC reductions been analyzed. The District must more fully evaluate the range of possible impacts to the RECLAIM market resulting from various shave levels.
>
> The SOx market is much more constrained in terms of market participants and trading, so any "lessons learned" from the NOx market may not be applicable. Thus, the PEA should consider and evaluate impacts due to market instabilities that are more likely in a constrained credit situation such as the current proposed rule.

3-26

In the DPEA, SCAQMD states (Table 1-1; P. 1-12), "According to both of the consultants' reports, a facility-by-facility evaluation was conducted which included an analysis of plot space availability. The analysis does not support the claim that there is not adequate plot space available to install SOx controls." While we understand that the District's consultants were instructed to look at control technology, it seems clear that key issues such as plot space and the requirements of a functioning refinery were not given adequate weight.

Design and layout of control technology including construction and installation needs are important constraints that must be considered. If the District's assumptions on layout are incorrect, it could mean that a lot more construction must be done which will have greater impacts. The District Staff should revisit their assumptions and environmental requirements associated with their proposed control technologies.

3-27

Comment 1-2: While companies will answer individually, it is clear that plot space limitations and related infrastructure requirements documented by company operators are both real and unaddressed. The PEA should analyze the impacts of actual plot space needs.

> We disagree with the Staff assertion that "the contractor analysis does not support the claim that there is not adequate plot space available to install SO_x controls." For example, the Norton Engineering Report (NE) cites examples where the location of proposed equipment needs to be modified due to operations needs [see p. 8-9]. Moreover, the collective experience of the refineries and their respective engineering contractors to design, construct, and operate refinery equipment is greater than that

3-28

associated with consultants retained to simply look at feasibility. Again, flawed assumptions relating to space requirements can adversely impact the analysis of construction costs and operating requirements.

3-28 Cont'd

"With regard to water demand impacts, SCAQMD staff recognizes that wet gas scrubber technology is water intensive. However, recycled water can be used in lieu of potable water. Specifically, up to 75 percent of the estimated increase in water demand due to the wet gas scrubbers under Option 1 of the proposed project can be satisfied with recycled water." [p. 1-13]

Comment 1-3: These statements are misleading. Although it is true that recycled water could likely be used in lieu of potable water, this can occur only if there is sufficient supply and infrastructure to supply the water to the affected facilities. The district must also consider whether building the additional infrastructure is feasible, both physically and economically.

Specific issues that need to be considered are: 1) the existence of a reliable supply of recycled water available to each facility 2) the existence of infrastructure, internal to each facility, to provide recycled water to the processes that would use the water 3) the capital cost to build the necessary infrastructure if it does not already exist and 4) to have a supply of recycled water available for use within the timeframe required for compliance.

3-29

Currently 8 out of 11 affected facilities "do not have access to recycled water" (see p. 3-67 in DPEA). While water purveyors are looking into the possibility of providing additional recycled water (i.e., the Harbor Refineries Recycled Water Pipeline Project (HRRWPP)), this does not necessarily mean that the specific RECLAIM facilities will have access and/or rights to it, or that water can be supplied in sufficient volumes.

The Staff should also analyze this issue on the basis that 8 of the 11 affected facilities have no current access to recycled water (see also comment 1-5 below).

"Implementation of the proposed project is expected to span over seven years, which should be adequate time for purchasing and installing wet gas scrubbers." [p. 1-14]

Comment 1-4: This assumption is speculative and leads to the underestimation of environmental impacts. While it is true that companies would tend to defer the more costly investments to the future, it is not clear that it would be the case for most companies. In fact, given the very aggressive reductions required in the first 3 years, and the uncertainty in the market, companies may need to reduce emissions in the short term – leading to high capital investments early in the compliance period rather than later as the District expects.

3-30

The District should evaluate a range of construction and installation schedules that vary from installation within 3 years to installation through the end of 2019.

"For water demand, there are three significance thresholds based on whether: 1) the total water demand of the proposed project is less than five million gallons per day 2) the existing water supply has the capacity to meet the increased demands of the proposed project and, 3) the potable water demand is a substantial use of water. The analysis shows that the increased potential demand for total water that may result from implementing the proposed project is not expected to exceed the significance threshold of five million gallons of total water demand per day.

3-31

Further, based on discussions with the local water suppliers, the existing water supply is expected to have the capacity to meet the increased demands of the proposed project. However, because the entire state of California is in the midst of a severe drought, a water supply analysis relative to the current and future availability of potable water and the use of recycled water and industrial-use groundwater to satisfy some of the water demand needs of the proposed project was conducted." [p. 1-24]

Comment 1-5: In analyzing the impact for CEQA, the district should analyze the worst-case scenario, which is that the demand would be on the potable water supply. While such an analysis could mean that the technology would become infeasible, the District must conduct a realistic environmental assessment and should not attempt to choose assumptions simply to justify its rule options.

Although the District does conclude by determining that potable water demand impacts are significant, the District Staff's summary of environmental impacts is inadequate given their review of the current water shortage in the State as described below: "However, back-to-back dry years and low reservoir levels have put California in a statewide drought. In late 2008, the state's major reservoirs were at about one-third of capacity, at a time when they would typically be at about two-thirds.

As a result, the DWR has allocated only 15 percent of requested amounts of water to be delivered to the SWP in 2009. This allocation is the second lowest in the history of the project. [1-18]… The [Governor's] proclamation further requested that all urban water users immediately increase their water conservation activities in an effort to reduce their individual water use by 20 percent [emphasis added].

3-31
Cont'd

In response to the Governor's proclamation, the California legislature has proposed Assembly Bill (AB) 49 – Water Efficiency[9] and Senate Bill (SB) 261 – Urban Water Efficiency[10]. These proposed bills will require a 10 percent reduction of urban water use by 2015 and 20 percent by 2020. However, these proposed bills will allow the use of non-potable or recycled water to count towards the progress in meeting these targets.

Water districts, in response to the drought, have also taken actions throughout the state such as: 1) asking for voluntary reductions 2) imposing mandatory restrictions or declaring a local emergency 3) imposing agricultural rationing 4) imposing drought rates, surcharges and fines 5) limiting new development and requiring water efficient landscaping and, 6) implementing a conservation campaign. [1-19][emphasis added]

Finally, the District's assertion that reclaimed water use can feasibly and cost-effectively displace an INCREASE in water use requirements in the face of mandated reductions of 20% in potable water can only be substantiated by a thorough analysis --- an analysis that was not conducted. The PEA should acknowledge the cross-media impacts and potential regulatory conflict of the proposed rule. The decision to determine that the impacts are significant does not release the District from analyzing the impacts fully.

Also, the conclusion that potable water impacts could be less than significant with mitigation implies incorrectly that 1) additional recycled water will be available for the specific facilities and 2) the facility has the ability to obtain written declarations from water purveyors that recycled water is not available [see mitigation measures GHG-2 (page 4-31) and HWQ-2 (page 4-84)].

6

In Tables 1-3 and 1-4, Options 1 and 2 of the preferred project show identical emission reductions for different FCCU control technologies. [p. 1-27 and 1-28]

> **Comment 1-6**: We do not understand why the District identified two options for FCCU SOx control with vastly different costs but equal emission reductions. We agree that De-SOx catalyst is less costly than installation of new Wet Gas Scrubbers (WGS); what is unclear is if the level of emission reductions achieved with De-SOx catalyst is equivalent to WGS. The equivalent emission reduction potential should be demonstrated and/or Option 2 analysis should be revised. This analysis should be revised to more clearly define the emission reductions and substantiating documentation. The current analysis is either incomplete or inaccurate.

3-32

Footnote 17 of Table 1-3 indicates the following regarding the potential 0.85 tpd reduction from refinery boilers/heaters: "… the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave." (emphasis added).

> **Comment 1-7**: It is not clear how the proposed RTC shave values were calculated. In addition, because the refinery heaters and boilers are not part of the proposed project, it should be clarified and justified why the "environmental impacts from such controls" are included as part of the project evaluation.
>
> What are the environmental benefits of including refinery heaters and boilers? What emission reductions could they displace? Under RECLAIM, substitution of more cost-effective controls on a site-by-site basis is encouraged, so what benefit is derived from including this specific choice within the Draft PEA?

3-33

EXISTING SETTING (CHAPTER 3)

Table 3-10 (p. 3-67) shows the existing water demand for the facilities that will be affected by the SOx shave.

> **Comment 3-1**: 8 out of 11 facilities have no access to recycled water (see our comments 1-3 and 1-5). In addition, we do not believe that the District's assumption that additional recycled water will be available for those specific facilities from the HRRWPP is correct – thus leading to an incorrect analysis of the impacts to this resource. Yet, the District proposes to offset the increase in use of potable water by expanded use of recycled water.
>
> The analysis should be based on the worst case scenario that none of the facilities specifically will have access to more recycled water, even if the HRRWPP is completed. At the very least, CEQA requires that the District assess the impacts of having to use potable water at those facilities.

3-34

ENVIRONMENTAL IMPACTS (CHAPTER 4)

Table 4-1 (p. 4-2) shows 0.85 tons per day (TPD) emission reduction for Refinery Heaters and Boilers.

> **Comment 4-1**: Refinery heaters and boilers were not included in the proposed rule because no new BARCT is being proposed for this source category. Inclusion of this class of sources within the DPEA is misleading and inappropriate. The CEQA mandates the evaluation of alternatives to the project, not alternatives to technology (i.e., wet gas

3-35

scrubbers) that may be evaluated (but ultimately rejected) as part of the project.

This option comes "out of left field" and there appears to be no documented basis within the context of the proposed rule and DPEA. Inclusion of this "alternative' weakens the DPEA by suggesting alternatives that are not covered by the proposed action.

3-35 Cont'd

Table 4-2 (p. 4-4) summarizes the options for control of the FCCU.

Comment 4-2: The District should document the basis for determining that De-SOx and Wet Gas Scrubbing can produce equivalent emission reductions. Such an analysis, using data from existing facilities (i.e., achieved in practice), is essential if the District is to assess adequately the environmental impacts associated with those technologies.

3-36

Under Option 1, 11 units may be retrofitted with one WGS each at eight facilities by December 31, 2018. Under Option 2, seven units may be retrofitted with one WGS each at five facilities by December 31, 2018. [p. 4-14]

Comment 4-3: It is not clear that these dates match the requirements in the Rule nor that this schedule has any relationship to how companies plan to comply with the final rule requirements. There is no basis for evaluating the potential construction impacts associated with installation of equipment on this schedule.

3-37

Cumulative Air Quality Impacts

"In general, the preceding analysis concluded that air quality impacts from any construction activities would be significant from implementing the proposed project because the SCAQMD's significance thresholds for construction will be exceeded for VOC, NO_x, and PM_{10}. Thus, the air quality impacts due to construction are considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, generate significant adverse cumulative air quality impacts." [4-24]

Comment 4-4: We concur that the proposed regulation (i.e., reduce RTCs by 55%) will cause significant environmental impacts. We believe that the district should consider Alternatives B and C that have much smaller impacts overall. It should be noted that those alternatives would cause significantly fewer environmental impacts (see p. 5-13 through 5-14) – particularly associated with water use and GHG impacts, while still achieving SOx emission reductions called for in the 2007 AQMP (Alternative B) or greater reductions similar to the proposed project (Alternative C).

3-38

Global Climate Change/GHG Impacts

The DPEA lists the following GHG mitigation measures:

"GHG-1 When SOx control equipment is installed and water is required for its operation, the facility operator is required to use recycled water, if available, to satisfy the water demand for the SOx control equipment.

GHG-2 In the event that recycled water cannot be delivered to the affected facility, the facility operator is required to submit a written declaration with the application for a Permit to Construct for the SOx control equipment, to be signed by an official of the water purveyor indicating the reason(s) why recycled water cannot be supplied to the project." [P. 4-31]

3-39

Comment 4-5: GHG-2 mitigation does not have any mitigating effect on GHG emission. Moreover, it mandates that the source gain a "written declaration" from the water purveyor that is inherently out of the control of the operator. Thus, this condition cannot be imposed on the facility operators (see also ES-4, ES-6, C 1). 3-39 Cont'd

"While there may be additional measures that could eventually be imposed on sources with potential increases in GHG emissions, CARB is adopting measures pursuant to AB 32 that would require the maximum technically feasible and cost-effective GHG emission reductions from most of the industry categories affected by the proposed project. CEQA Guidelines §15364 defines 'feasible' as 'capable of being accomplished in a successful manner within a reasonable period of time…' Specifically, CARB's adopted 'early action measures' include a measure to limit methane emissions from landfills, which SCAQMD staff will enforce." [pp. 4-33 to 4-34]

Comment 4-6: The District's assertion that AB 32 projects will serve as mitigation to the GHG emissions that could be caused by the project makes no sense. Notwithstanding the current uncertainty concerning the ultimate levels of emission reductions, the timing of the reductions, or even how those emission reductions will be achieved, it is unclear how GHG emissions achieved under AB 32 would qualify as mitigation.

The District's approach is incomplete and not helpful in developing approaches that can be used in the subsequent permitting required by projects in order to comply. Issues such as the applicability of BACT, NSR, PSD as well as the effect of EPA's Tailoring Rule (p. 4-33 ff) are unresolved and cannot be resolved before permitting begins.

Hence, projects that are required to comply with the proposed action, and the District as well, would be faced with a Gordian Knot. Again, this issue argues for Alternative B or C that will have many fewer environmental impacts while still resulting in SOx emission reductions called for in the 2007 AQMD (Alternative B) or greater reductions similar to the proposed project (Alternative C). The DPEA is inadequate because it has not identified feasible and reasonable mitigation measures to address GHG impacts. 3-40

"Therefore, GHG BACT is at least as stringent as CEQA's definition of feasible mitigation, which similarly allows consideration of economic, technological and environmental factors. Thus, application of BACT will require the maximum feasible reductions of GHGs at new or modified sources." [p. 4-35]

Comment 4-7: How has the District determined the relationship of GHG BACT to CEQA? No one in USEPA, CARB, or the District has documented the findings, requirements, conditions, emission control efficiencies or technology associated with BACT for GHGs. Even if this is true, it is speculative to assert that BACT for GHGs is as stringent as CEQA mitigation requirements. 3-41

Energy Impacts

"In summary, the energy impacts from both Option 1 and Option 2 of the proposed project are concluded to be less than significant." [p. 4-42]

Comment 4-9: The District did not include in its analysis the additional energy needed to pump potable water (rather than recycled water) to 8 of the 11 facilities that likely will not be able to utilize recycled water to meet the requirements of the rule. This should be included in the PEA. 3-42

Barbara Radlein
October 1, 2010
Page B-7

Hydrology – Water Impacts

"Level of Significance After Mitigation: The analysis shows that proposed increase in total water use under both Option 1 and Option 2 cannot be fully supplied with recycled water (either currently or in the future) and non-potable groundwater and that some potable water may still be required for certain facilities. While the potentially adverse water impacts can be reduced to below significance if facility operators are required to use current and future supplies of recycled water, if available, there is no absolute guarantee at the time of this writing that future supplies of recycled water will be available to the affected facilities included in the HRRWPP Project.

While the use of recycled water can help reduce the water demand impacts substantially, the overall water demand will not be completely mitigated. Therefore, the proposed project will remain significant after mitigation for water demand." [p. 4-84] 3-43

Comment 4-10: Here the District acknowledges that Options 1 and 2 cannot be fully supplied with recycled water. Even if the District Staff concludes the impact will be significant, it does not relieve them of the responsibility to analyze the most likely scenario. The PEA should also analyze the impacts if existing and/or foreseeable water use regulations significantly impede the facilities' use of potable water.

Comment 4-11: As in mitigation measure GHG-2, mitigation measure HWQ-2 mandates that the source gain a "written declaration" from the water purveyor that is inherently out of the control of the operator. Thus, this condition cannot be imposed on the facility operators (see also Comments ES-4, ES-6, C 1). The PEA should identify feasible and reasonable mitigation measures. 3-44

Cumulative Hydrology and Water Quality Impacts: Because the project-specific water demand impacts under Option 1 have been concluded to be significant due to the 500DU potable water demand criteria and in consideration of California's on-going drought and that 100 percent of the potential increase in water use cannot be supplied by recycled water, it could be argued that the proposed project is cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1). Therefore, the proposed project is expected to generate significant adverse cumulative water demand impacts.

However, because the project-specific water quality impacts do not exceed any applicable significance thresholds, they are not considered to be cumulatively considerable pursuant to CEQA Guidelines §15064 (h)(1) and therefore, do not generate significant adverse cumulative water quality impacts." [pp. 4-84 to 4-85] 3-45

Comment 4-12: WSPA agrees that with the water demand impacts of the project will be cumulatively significant. Even if the District concludes the impacts will be significant, it does not relieve them of the responsibility to analyze the most likely scenario – no additional supplies of recycled water for the RECLAIM facilities. The PEA should also analyze the impacts if existing and/or foreseeable water use regulations significantly impede the facilities' use of potable water. (See also comment 1-3, 1-5)

"Cumulative Mitigation Measures: The potentially adverse water impacts can be reduced further than initial estimates if recycled water is employed for WGS installations. Even with the use of recycled water as part of the implementing the proposed project, the analysis shows that 100 percent of the proposed increase in total water demand cannot be fully offset by the use of recycled water. While the use of recycled water can help reduce the water demand impacts substantially, the overall total water demand will not be completely mitigated. Therefore, the 3-46

10

proposed project will remain cumulatively significant after mitigation for water demand." [p. 4-85]

Comment 4-13: WSPA agrees with the significance determination but believes the impact analysis should be done assuming no future increases in recycled water. GHG-2 mitigation condition mandates that the source gain a "written declaration" from the water purveyor that is inherently out of the control of the operator.

Thus, this condition cannot be imposed on the facility operators (See also comments 1-3, 1-5, C-1), because its assumption that all the facilities would have access to increased supplies of recycled water is not the likely worst-case scenario as RECLAIM facilities will not have certain access to any new supplies.

3-46 Cont'd

ALTERNATIVES (CHAPTER 5)

Alternatives and BARCT Determination

Please note that Options 1 and 2 of the preferred project are not fully specified in Table 5-1. [p. 5-2]

Comment 5-1: Options 1 and 2 need to be more clearly defined in Table 5-1 because Option 2 is not sufficiently defined to indicate exactly how it (if it in fact can) achieve the same emission reductions. It is not clear how the two Options result in the same emission reductions for different projects and costs. More description of Option 2 and how equivalent emissions reductions can be achieved is needed.

3-47

Footnote 91 of Table 5-1 indicates the following regarding the potential 0.85 tpd reduction from refinery heaters and boilers: "… the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave." (emphasis added)

Comment 5-2: It is not clear how the proposed RTC shave values were calculated. In addition, the refinery heaters and boilers are not even included as part of the proposed project. See Comment 4-1[1].

3-48

In Table 5-2, Options 1 and 2 for Alternative C list SOx emission reductions for Refinery heaters and boilers of 0.85 tpd under "Decreases total operational SOx emissions by 5.48 tpd as follows…"[p. 5-3]

Comment 5-3: The project description for Alternative C on page 5-13 does not include these units as part of the project. Emission reductions associated with these units should not be included as part of the reduction scenario. (See comment 5-2 and 4-1 above)

3-49

[1] *Comment 4-1 Refinery heaters and boilers were not included in the proposed rule because no new BARCT is being proposed. Inclusion of this class of sources within the DPEA is misleading and inappropriate. The CEQA mandates the evaluation of alternatives to the project, not alternatives to technology (i.e., wet gas scrubbers) that may be evaluated (but ultimately rejected) as part of the project. This option comes "out of left field" and there appears to be no documented basis within the context of the proposed rule and DPEA. Inclusion of this "alternative' weakens the DPEA by suggesting alternatives that are not covered by the proposed action.*

Under "Energy Impacts Significant" for the proposed project Option 1 states "the reduction in the use of natural gas is not as much as the proposed project – Option 2" and for proposed project Option 2 states "the reduction in the use of natural gas is more than the proposed project – Option 1". [p. 5-7]

Comment 5-4: These statements are inconsistent with the numbers shown in the Table 2 under "Energy" on page 5-6 which states for both proposed project options "overall reduction in the use of natural gas by 4.1 MMBTU/day." Natural gas reductions for Alternative C (both options) were listed as 34.25 MMBTU/day, eight times greater than the proposed project.

3-50

"…the operation GHG emissions would be less than both Options 1 and 2 of the proposed project. In addition, less than significant adverse secondary impacts for aesthetics, energy, hazards and hazardous materials, hydrology and water quality, and transportation and traffic are expected to result from implementing Alternative C, but these impacts would be less than both Options 1 and 2 of the proposed project." [p. 5-14]

Comment 5-5: Given that less impacts result from implementation of Alternative C while still reducing SOx emissions, it is not clear why Alternative C is not the proposed project, since the SOx reductions are similar (5.48 vs. 6.21 tpd) and the proposed project reductions are far more uncertain.

3-51

"In summary, if Alternative C were implemented, less SO_x reductions would be achieved and less health benefits from reducing SOx overall will be realized." [p. 5-20]

Comment 5-6: An assessment of the difference in health benefits between the proposed project and Alternative C has not been conducted. A linear relationship between increased reductions in SOx and health benefits cannot be assumed for reductions beyond those included in the 2007 AQMP without further multi-pollutant, photochemical modeling analysis. Therefore, to state that there will be additional health benefits from the proposed project versus Alternative C, which provides less significant impacts than the proposed project, is unsubstantiated.

3-52

"However, for Alternative C - Option 2, the adjusted estimate for increased potable water demand would be 108,436 gallons per day, which is below the minimum amount of potable water needed to qualify for as a water demand project per the 500 DU calculations (e.g., 133,911 gallons per day). Thus, for this reason, Option 2 of Alternative C is expected to contribute to less than significant adverse water demand impacts." [p. 5-65]

Comment 5-7: As WSPA stated earlier, we still believe that the District should analyze potable water demand without assuming the facilities will be able to access new and/or greater amounts of potable water.

3-53

"Further, even though Alternative C would require less WGSs to be installed and would require less total water overall, both Option 1 and Option 2 of Alternative C are estimated to have equivalent demands of potable water when compared to Option 1 and Option 2 of the proposed project. With regard to water quality, both Option 1 and Option 2 of Alternative C would generate less wastewater than Option 1 and Option 2 of the proposed project, respectively. Overall, Alternative C has less environmental impacts than the proposed project." (emphasis added) [p. 5-83]

3-54

Comment 5-8: We agree that Alternative C, particularly without inclusion of the unused RTCs, has less environmental impact than the proposed project. We do not believe that the impacts of the District's seizure of "unused" RTCs have been adequately assessed. Aggressive shave reductions will force facilities to alter operations (i.e., over-control) leading to the installation of additional emissions control equipment with attendant costs and environmental impacts.

3-54 Cont'd

"… but it does not achieve the additional SOx reductions and health benefits expected from the proposed project." [p. 5-83 emphasis added]

Comment 5-9: This statement is misleading. Aerosol particulate formation is a highly non-linear process, dependent on a complex location and aerometric conditions. NO additional air quality or health benefits beyond the AQMP have been documented because the analysis has not been done (see Comment 5-6 above). The District should note that even Alternative C, without inclusion of the unused RTCs, results in greater emission reductions than the AQMP.

What the District must do if it wishes to document the need for, and benefit of additional emissions reduction beyond what has been specified in the AQMP, is to conduct an appropriate modeling analysis of the air quality and health impacts associated with more aggressive emission reductions. Without such information, the DPEA is incomplete.

Without the proper analysis, the district's conclusion, that emissions beyond those required by the AQMP can lead to measurable improvements in air quality at the desired monitoring stations is speculative.

3-55

Barbara Radlein
October 1, 2010
Page C-1

ATTACHMENT C: MINOR COMMENTS

WSPA offers the following minor comments on the DPEA, which do not affect the overall assessment of the proposed project or the alternatives, but which are editorial or typographical in nature.

Comment: The air quality and hazardous materials impacts related to sodium hydroxide (NaOH) usage for Alternative B (Table 5-2, p. 5-5, 3rd bullet and p. 5-7) indicate that the impact from increased NaOH usage is "less than the proposed project – Option 1, but equivalent to the proposed project – Option 2" (emphasis added). However, the increase in NaOH usage listed in the table on the previous page (5.45 tpd) is less than the NaOH increases for both options of the proposed project (13.24 tpd and 8.79 tpd for Options 1 and 2, respectively). This apparent inconsistency needs to be corrected. 3-56

Comment: The GHG impacts for Alternative C – Option 1 column (Table 5-2, p. 5-5, 2nd bullet) indicates that the GHG emissions increase is "significant for GHGs, but less than proposed project for both Options 1 and 2." However, although the emissions for Alternative C are less than those for proposed project Option 1, the GHG emissions increase for Alternative C – Option 1 (34,159 MT/yr without mitigation; 33,911 MT/yr with mitigation) is actually greater than proposed project – Option 2 (19,662 MT/yr without mitigation; 19,580 MT/yr with mitigation). Please make this update to Table 5-2, Alternative C - Option 1. 3-57

Comment: The impacts due to traffic for the proposed project (both Options 1 and 2) listed in Table 5.2 (p. 5-9) indicate that the impacts are different under both the construction and operation scenarios; however, the number of construction trips listed in the table (700 trips) is the same for both options of the proposed project, and therefore, this comment is inconsistent with the numbers shown in the table. 3-58

Comment: There also appears to be a typographical error on p. 5-20 of the DPEA, where it references the number of wet gas scrubbers that would be installed under Alternative C – Option 1. The last paragraph on p. 5-20 indicates that this alternative has a total of eight add-on controls, of which six are wet gas scrubbers; however, other references in this chapter of the DPEA indicate that there would be eight wet gas scrubbers installed under this alternative, for a total of ten add-on controls. 3-59

Comment: On the top of page 5-34, the increase in diesel and gasoline is stated as follows: "For Alternative C – Option 1, the analysis shows an overall increase in diesel and gasoline use of approximately 2,410 gallons per day and 1,384 gallons per day, respectively. Similarly for Alternative C – Option 2, the analysis shows an overall increase in diesel and gasoline use of approximately 2,180 gallons per day and 1,384 gallons per day, respectively."

However, the numbers listed in Table 5-25 at the bottom of the same page indicate that the total diesel and gasoline uses for Alternative C – Option 1 are 3,063 gallons per day and 1,354 gallons per day, respectively, and for Alternative C – Option 2 are 2,690 gallons per day and 1,354 gallons per day, respectively. The numbers should be updated as appropriate. 3-60

Comment: For the Alternative C, peak daily water use during construction listed in Table 5-1 appears to be a typo. It should not be the same as the proposed project (52,272 gal/day, p 4-67) but rather 66,000 gal/day (p-5-57). 3-61

Comment: Footnote 12 is missing from Table 1-3. Please add it to the table as it is critical information. 3-62

14

Responses to Comment Letter #3
(Western States Petroleum Association, October 1, 2010)

3-1 SCAQMD staff appreciates the effort made by WSPA in their commitment to follow the January 2010 Work Plan. The collaborative working relationship is also greatly appreciated.

3-2 SCAQMD staff has evaluated the proposals submitted by WSPA regarding the SOx shaves ranging from 25 to 40 percent. However, based on SCAQMD staff's assessment of available control technologies, the WSPA proposals do not appear to qualify as Best Available Retrofit Control Technology (BARCT) in accordance with California Health and Safety (H&S) Code §40440 as well as equivalency to command-and-control regulations, as required under H&S Code § 39616(c)(1). In addition, the SCAQMD's proposal for a 55 percent shave reflects the modifications to the SCAQMD's original proposal of a 67 percent shave made in response to discussions with industry with regard to determining BARCT. SCAQMD seeks the maximum achievable SOx reductions from the proposed project to ensure attainment of the annual PM2.5 standard, since SOx reductions are 15 times more effective than NOx reductions in reducing PM2.5 concentrations. Moreover, future attainment of the 24-hour PM2.5 and revised annual PM2.5 standards will require even greater SOx emissions reductions for attainment. Without sufficient SOx reductions from the proposed project, which is a control measure in the 2007 AQMP, the SCAQMD may have difficulty attaining the revised annual PM2.5 standard. With regard to economic impacts of the proposed project, refer to Response to Comment 3-5. See also the Socioeconomic Impact Report for the proposed project.

3-3 Individual responses to the detailed comments submitted have been prepared and begin with Response to Comment 3-4.

3-4 If the proposed project is adopted, SCAQMD staff has concluded that there would be sufficient SOx RTCs available to maintain trading within the SOx RECLAIM program. This conclusion is based on a 25 percent difference between facility holdings and emissions. In addition, the proposed shave incorporates a 10 percent compliance margin and a safety valve where RTCs are released back to the market in case the RTC price exceeds a $50,000/ton threshold. All of these rule components will assist in maintaining trading within the SOx RECLAIM program.

3-5 The independent consultants, ETS and NEXIDEA, were selected by a four member panel including representatives from the SCAQMD as well as from WSPA. WSPA's member refineries were in agreement with the selected consultants and they were fully paid for by the refineries. The consultants started their project in September 2008. After considerable amount of time spent at the site visits to all six refineries discussing technical issues such as space limitations, utility infrastructure, control technologies, BARCT levels, and time needed for the refineries to install control technologies considering equipment downtime, the consultants finalized their independent studies in April 2009. During this nine-month period working closely with the refineries, the consultants sent their draft analyses to the refineries at least four times for input and comments, and the consultants addressed all the comments received before the reports were finalized. The consultants' team of engineers

carefully listened to all comments and input from the refineries, and incorporated the refineries' input, if technically sound and correct, in their final feasibility and cost analyses.

In March 2010, as part of the Work Plan developed by SCAQMD staff in concert with WSPA representatives, SCAQMD staff hired Norton Engineering Consultants (NEC) to review ETS's and NEXIDEA's analyses. (It should be noted that NEC applied for this project in 2008 together with ETS and NEXIDEA. NEC received the highest score from WSPA in 2008 but was not selected because their bid was higher than the budget allowable in 2008. NEC has also done work for several refineries.) Generally, NEC estimates for capital costs and annual maintenance costs were higher than ETS and NEXIDEA. However, for the FCCU's WGSs, NEC was in close agreement with ETS. Because NEC's estimates for costs were higher than ETS and NEXIDEA, NEC recommended SCAQMD staff to re-estimate the cost-effectiveness values for the project. SCAQMD staff did so and their re-estimated cost-effectiveness values based on NEC's recommendations are presented in Chapter 12, Section 12.2 of the Staff Report. The table below provides a comparison between ETS, NEXIDEA and NEC's estimates:

	ETS/AEC, NEXIDEA	**NEC**
Present Value for 25 Years	$630 million	$738 million
Emission Reductions	4.36 tons per day*	4.21 tons per day*
Cost Effectiveness	15,845 $/ton	19,199 $/ton

*Early reduction was 1 ton per day, applicable to a refinery that installed and operated a WGS for their FCCU since 2008, and a refinery that conducted process modification to their SRU/TGU to reduce emissions pursuant to EPA consent decree. The emission reductions from this FCCU and this SRU/TGU accounted for from 2005 baseline were 1 ton per day. The total emission reductions estimated from 2005 baseline are about (4.36+1=5.36 tons per day) for ETS/NEXIDEA and 5.21 tons per day for NEC.

ETS/AEC and NEC estimated that the actual emission reductions estimated from the 2005 baseline that could be cost-effectively achieved for this project are approximately 5.21 tons per day to 5.36 tons per day. However, to achieve these actual reductions, excess RTCs or "unused" RTCs must be removed to prevent avoidance of installing controls. Thus, SCAQMD staff has estimated that 6.1 tons per day of RTC reductions must be made in order to achieve these actual reductions. The amount of excess or "unused" RTCs estimated for the 2005 baseline was 1.73 tons per day (i.e., the difference between the RTC holdings of 11.77 tons per day and the 2005 audited emissions of 10.04 tons per day) can be counted towards the goal of 6.1 tons per day RTC reductions at no cost to the facilities. In other words, if RECLAIM facilities agree to reduce all "unused" RTCs, the "real" compliance costs to achieve a programmatic 6.1 tons per day RTC reductions could be less than $630 to $738 million estimated by the consultants. WSPA's assessment that the "*The District's overly aggressive proposal incorporates the seizure of "unused" RTC's in a manner that doubles the compliance cost. The costs to achieve emission reductions required by the proposed shave are nearly double the costs required to achieve emission reductions equivalent to installation of BARCT controls on refinery sources*" does not make sense.

With regard to the comment that the Draft PEA should evaluate the costs of achieving BARCT levels, see Response to Comment 1-1.

3-6 The proposed project and Alternative C have identical, significant adverse water demand impacts. With regard to GHG emissions, the analysis for the proposed project indicates the

quantity of GHG emissions would be greater than those analyzed for Alternative C (i.e., by approximately 5,000 MT CO2eq/year), but both the proposed project and Alternative C are shown to have significant adverse impacts for GHG emissions. While there are mitigation measures to help minimize the impacts for water demand and GHGs, the mitigation will not bring the impacts below the applicable significance thresholds (using recycled water can reduce GHG emission impacts up 40 percent in northern California to as much as 81 percent in southern California[24] because less energy is required to collect, treat, and redistribute to the point of use). For these reasons, SCAQMD staff has prepared a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan. This document, referred to as "Attachment 1 to the Resolution," will be included in the Governing Board package.

In addition to Alternative C, SCAQMD staff considered two other alternatives: Alternative A (the "no project" alternative) and Alternative B (the AQMP alternative). While both Alternative A and Alternative B were shown to have less environmental impacts than the proposed project and Alternative C, neither was shown to achieve the goals of the proposed project. Specifically, Alternative A, the 'no project' alternative, does not achieve the goals of the proposed project because it does not implement the AQMP control measure. While no significant adverse secondary environmental impacts would result from the 'no project' alternative, it is not necessarily the environmentally superior alternative in accordance with CEQA Guidelines §15126.6(e)(2) because SOx emissions would continue to be emitted at current levels, thus, not improving air quality in the District.

While less add-on control equipment would be installed overall under Alternative B when compared to the proposed project, the environmental impacts would be less than significant and substantially less than the proposed project but the potential SOx emission reductions would also be less. Because Alternative B is limited to fewer source categories, fewer WGSs would be installed. Of the adverse environmental impacts that would be generated under Alternative B, the impacts would be less than the proposed project and less than significant, except for air quality construction emissions which are identical to the proposed project and are concluded to be significant. Alternative B, with a potential SOx emissions reduction of 1.50 tons per day, only partially achieves the SOx emission reductions identified in the AQMP, which are necessary to demonstrate attainment with state and federal air quality standards. When compared to the proposed project, Alternative B provides fewer benefits to air quality and public health.

Alternative C, with a potential SOx emissions reduction of 5.48 tons per day, achieves slightly less potential SOx emission reductions than the proposed project. When compared to the proposed project, the GHG emissions projected for both options of Alternative C are significant, but less than the proposed project. Because Alternative C employs the same amount of NaOH for Option 1 and Option 2, respectively as the proposed project, it has equivalent toxic impacts when compared to the proposed project. Further, even though Alternative C would require less WGSs to be installed and would require less <u>total</u> water overall, both Option 1 and Option 2 of Alternative C are estimated to have equivalent demands of potable water when compared to Option 1 and Option 2 of the proposed project. Thus, Alternative C has equivalent potable water demand impacts as the proposed

[24] California Air Pollution Control Officers Association (CAPCOA), Quantifying Greenhouse Gas Mitigation Measures, August 2010.

project. With regard to water quality, both Option 1 and Option 2 of Alternative C would generate less wastewater than Option 1 and Option 2 of the proposed project, respectively. Overall, Alternative C has less environmental impacts than the proposed project but it does not achieve the additional SOx reductions and health benefits expected from the proposed project.

3-7 The comment states that if Alternative C was selected in lieu of the proposed project, a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan may not be necessary. The analysis for Alternative C was shown to also have significant adverse impacts for air quality during construction, GHGs, and water demand, even after mitigation measures are employed. Further, the air quality and water demand impacts for Alternative C are identical to the proposed project. For these reasons, if Alternative C was selected, a Statement of Findings, a Statement of Overriding Considerations, and a Mitigation Monitoring Plan would also be required. However, Alternative C was not selected because even though it has less environmental impacts than the proposed project it does not achieve the additional SOx reductions and corresponding health benefits expected from the proposed project and does not achieve what the SCAQMD staff's analysis concludes to be BARCT.

3-8 WSPA's assessment related to NEC's report, for cement kilns and sulfuric acid plants, which was incorporated into the analysis, is addressed below.

Cement Kilns

NEC review on cement plants on page 7 of NEC's report states, "*The control technology selection [ETS]… for the cement manufacturing plant kiln is not yet commercially proven… NEC expects the cost for wet scrubbing technology to be more cost effective…….*"

On page 10, NEC states, "…*The original estimate did not add any project scope contingency. NEC revised the estimate by adding the required additional ductwork for the new plot location and the project contingency……The original cost (without project scope contingency) was $19.6M and it would rise to $32.7M if project scope contingency equivalent to that used for the FCC scrubbers …is added.*"

SCAQMD staff's estimates of cost effectiveness for cement kilns based on NEC's recommendation are shown in Section 12.2, Chapter 12 of Part 1 of the Staff Report. The following table shows a comparison between the numbers developed based on ETS's and NEC's recommendation:

	ETS	**NEC**
Capital Costs	$19.6 million	$32.7 million
Present Values	$43.7 million	$62 million
Cost Effectiveness	$19,300 per ton	$26,824 per ton

The costs estimated by NEC were higher than those of ETS. However, the control technology selection of ETS, estimated by NEC, was still cost-effective.

SCAQMD staff acknowledges that the control equipment selection made by ETS (i.e., hybrid limestone scrubber) has not yet been installed at a cement manufacturing facility,

however the technology is feasible and cost-effective, and therefore, ETS's recommendation satisfies the BARCT requirements of the H&S Code. Furthermore, NEC recommended wet gas scrubbing as an alternative control technology. NEC indicated that WGS is even more cost-effective than the technology recommended by ETS. Under the RECLAIM program, the cement manufacturing facility is not required to use the technology recommended by ETS, and may select to use WGS, or any other technologies to reduce their emissions so that they can be in compliance with the shave.

Sulfuric Acid Plants

NEC review on sulfuric acid plant on page 7 of NEC's report states, *"The original costs for installation of scrubbers on the sulfuric acid plant .....appear to be underestimated by a factor of 2.5 to 3.*"

Adjusting the costs upward as recommended by NEC, the costs and cost-effectiveness for the sulfuric acid plants were shown in the following table and are compared to NEXIDEA's estimates:

	NEXIDEA	**NEC**
Capital Costs	$ 7 million	$20 million
Present Values	$19 million	$32 million
Cost Effectiveness	$2,016 per ton	$3,431 per ton

Thus, both consultants believe that WGS technology is a feasible method of SOx control for sulfuric acid plants, and cost-effective even using NEC assumptions.

3-9 The Draft PEA concluded that air quality impacts during construction would be significant, while air quality impacts related to the operation of necessary control equipment and related processes would be less than significant. However, the analysis in the Draft PEA showed an increase in criteria pollutants during both construction and operation activities, and these increases can be attributed to construction equipment, worker vehicle trips and on-road truck trips associated with delivery and hauling activities, and not stationary sources. Emissions from construction activities are not subject to offset requirements pursuant to Regulation XIII – New Source Review. Further, the construction worker vehicle trips and operational truck trips do not qualify under the mobile source criteria that would require the emissions to be accumulated and offset pursuant subdivision (g) of Rule 1306 – Emission Calculations. Thus, no offsets would be required for these activities.

When making findings as required by Public Resources Code §21081 and CEQA Guidelines §15091, the lead agency must adopt a reporting or monitoring program for the changes to the project which it has adopted or made a condition of project approval in order to mitigate or avoid significant effects on the environment (Public Resources Code §21081.6 and CEQA Guidelines §15097(a)). To fulfill the requirements of Public Resources Code §21081.6 and CEQA Guidelines §15097, the SCAQMD has developed a mitigation monitoring plan for anticipated impacts resulting from implementing the proposed project. The mitigation measures developed to mitigate the air quality impacts of the proposed project contain standard requirements that have been consistently applied for both SCAQMD rule projects and projects where the SCAQMD is the lead agency. In addition, because of the significant adverse water demand impacts, two additional

mitigation measures were included to require the use of recycled water to mitigate the use of potable water, and the GHGs that may otherwise be generated from utilizing potable water.

Lastly, regarding the applicability of Regulation XVII – Prevention of Significant Deterioration (PSD), based on the quantity of estimated emissions, no component of the proposed project is expected to meet or exceed the annual emissions thresholds outlined in subdivision (s) of Rule 1702 – Definitions. This conclusion is based on the fact that operational criteria pollutant emissions from all affected facilities (Final PEA, Chapter 4, Table 4-7) would be less than the significant increase levels for major sources Rule 1702(s) and shown in the table below. Therefore, PSD would not apply to the proposed project.

	Rule 1702(s) Significant Increase Level	
Pollutant	Tons per Year	Pounds per Day
Carbon Monoxide	100	548
Sulfur Dioxide	40	219
Nitrogen Oxides	100	548
Particulate Matter	25	137
PM10	15	82
Volatile Organic Compounds	40	219

Any permit application submitted by an owner or operator of a facility to install new equipment or modify existing equipment in response to the proposed modifications to the SOx RECLAIM program will be individually evaluated by SCAQMD staff to determine, what, if any, emission increases or decreases would occur, and what applicable SCAQMD rules and regulations would apply as part of the engineering review and permitting process. Permit applications will also be evaluated to determine whether or not the SOx reduction strategies listed in the permits are identified in the PEA for the proposed project and environmental impacts have been analyzed. To the extent that no new control strategies or unique facility characteristics are identified in the permit applications, further environmental analysis would likely not be required. If new SOx control strategies or unique facility characteristics are identified that were not evaluated in the PEA, further environmental analyses may be required. Finally, at the time an application is issued a permit to construct, the mitigation measures outlined in the Mitigation Monitoring Plan would be included as part of the permit conditions. The analysis in the PEA should be able to support permit applications within the scope of the project. Pursuant to current standard practice, SCAQMD staff would evaluate the individual permit applications to determine if any additional CEQA analysis would be required.

3-10 SCAQMD staff has evaluated the proposals by WSPA to increase the amount of the proposed SOx RTC shave, but does not believe that the newly proposed RTC shave would achieve the required BARCT reductions. As a result, SCAQMD staff continues to support the proposed project, which reflects BARCT in accordance with H&S Code §40440 as well as equivalency to command-and-control regulations, as required under H&S Code

§39616(c)(1). Also, the SCAQMD has reduced its initial shave proposal in response to industry concerns regarding costs.

3-11 Under the RECLAIM program, affected facilities have the flexibility to install air pollution control equipment, change method of operations, or purchase RTCs to meet BARCT levels. As such, the Draft PEA analyzes multiple scenarios that illustrate the worst-case effects of applying the various SOx control technologies along with demonstrating the flexibility that is provided by the RECLAIM program to facility operators when it comes to choosing the methods for reducing SOx emissions. Because of the program's built-in flexibility, as a practical matter, there is no way to predict what each facility owner/operator will do. The various alternatives, including the 2007 AQMP analysis (referred to as Alternative B in the Draft PEA), were designed to evaluate the worst-case options available based on the consultants' reports.

3-12 The environmental impacts of the proposed RTC shave are impacts that would occur as a result of facility operators making physical modifications to reduce SOx emissions overall or using unused RTCs (see Response to Comment 3-5). These impacts to air quality (including GHG emissions) and water use, as well as several other environmental topics identified in the NOP/IS, have already been analyzed in the Draft PEA for the proposed project and the alternatives. Further, the socioeconomic effects of the proposed project and the alternatives have also been analyzed and can be found in the socioeconomic report. Moreover, SCAQMD staff has provided a 10 percent margin to help facilities ensure compliance. In addition, the proposed amendments include several safety valves to prevent potential facility shutdowns: 1) gradual annual reductions with extended compliance schedule (from 2012 to 2019); 2) monitoring RTC price trends over a 12-month rolling average; 3) hold public hearing if RTC price exceeds $50,000 per ton (discrete price); and 4) ability for the Governing Board to set aside (give back) up to 100 percent of RTC reductions for any year when RTC price exceeds $50,000 per ton.

ETS/AEC and NEC estimated that the actual emission reductions estimated from the 2005 baseline that could be cost-effectively achieved for this project are approximately 5.21 tons per day – 5.36 tons per day. However, to achieve these actual reductions, excess RTCs or "unused" RTCs must be removed to prevent avoidance of installing controls. Thus, SCAQMD staff has estimated 6.1 tons per day of RTC reductions must be made to achieve these actual reductions. The amount of excess or "unused" RTCs estimated for the 2005 baseline was 1.73 tons per day (i.e., the difference between the RTC holdings of 11.77 tons per day and the 2005 audited emissions of 10.04 tons per day) can be counted towards the goal of 6.1 tons per day RTC reductions at no cost to the facilities. In other words, if RECLAIM facilities agree to reduce all "unused" RTCs, the "real" compliance costs to achieve a programmatic 6.1 tons per day RTC reductions could be less than $630 to $738 million estimated by the consultants.

3-13 SCAQMD staff's estimates of cost-effectiveness based on NEC's recommendations are in Chapter 12, Section 12.2 of the Staff Report, and a comparison of the cost-effectiveness based on NEC/AEC, NEXIDEA and NEC is also Chapter 12, Section 12.3 of the Staff Report. With regard to the comment suggesting that the costs and cost-effectiveness analyses should be included in the Draft PEA, see Response to Comment 1-1.

3-14 The comment states that the need for additional water supplies was not adequately analyzed in the Draft PEA. The total water demand for each source category and each facility for the proposed project and alternatives was quantified and compared to the CEQA significance criteria for water demand. There is a comprehensive analysis of water demand impacts in Chapters 4 and 5 of the PEA and the impacts are summarized in several tables throughout the Draft PEA (e.g., Tables 4-41, 4-42, 4-43, 4-44, 5-38, 5-45, 5-46, 5-47 and 5-48). Detailed calculations supporting the analysis of water demand impacts are included in Appendix B. Further, the quantities and availability of potable water, industrial use water (groundwater) and recycled water that may be needed to implement the proposed project were carefully analyzed facility-by-facility and in cooperation with each facility's water supplier. In addition, water supply data were provided by each of the individual facility operators as a part of a survey and relied upon in the hydrology/water quality analysis in the Draft PEA. A comprehensive analysis of the availability of the various types of water identified here was also prepared in Chapters 4 and 5 of the PEA and the analysis is summarized in several tables throughout the Draft PEA that define the type and amount of water that may be needed to implement the proposed project (e.g., Tables 4-45, 4-46, 4-47, 4-48, 5-39, 5-40, 5-41, 5-49, 5-50, 5-51, and 5-52). The amount of potable water that may be required is within the range of what was considered to be a substantial use of potable water.

The Draft PEA includes a comprehensive evaluation of the use of recycled water as a viable substitute for potable water. Based on input from the various recycled water purveyors, the Draft PEA makes a distinction between the facilities that currently have access to recycled water and those that do not. The Draft PEA also identifies those facilities that currently do not have access to recycled water, but are earmarked to receive future access to recycled water as a result of the anticipated 2013 completion of the Harbor Refineries Recycled Water Pipeline Project (HRRWPP)[25]. Representatives from both the Los Angeles Department of Water and Power (LADWP) and West Basin Municipal Water District (WBMWD) have provided detailed information about the availability of future access to recycled water to specific facilities that may also be affected by the SOx RECLAIM project. Further, these representatives have assured SCAQMD staff that there is an over-abundance of reliable recycled water ready for use. The EIR prepared for the HRRWPP project contains a detailed analysis of the environmental impacts and costs associated with building the pipeline extensions to the existing recycled water infrastructure. Because these impacts are already accounted for in the EIR for the HRRWPP, SCAQMD staff has incorporated by reference the environmental and cost impacts of the Final EIR for the HRRWPP project into the PEA prepared for the proposed project pursuant to CEQA Guidelines §15150. While the PEA for the proposed project incorporates by reference the impacts of building the HRRWPP infrastructure, the PEA includes an analysis of potentially significant adverse impacts from tying in to the HRRWPP infrastructure. Therefore, between the Final EIR for the HRRWPP and the PEA for the proposed project adverse cost and environmental impacts from constructing the HRRWPP and each facility tying in to the HRRWPP have been comprehensively analyzed.

Finally, it should be emphasized here the Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably

[25] Final EIR available online at: http://www.ladwp.com/ladwp/cms/ladwp012729.pdf.

foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Even though the HRRWPP is under construction, it has not yet been fully completed and as such, the affected facilities have not yet tied into the system. For this reason, the PEA does not assume that recycled water will be available and the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For these reasons, potable water demand was found to be significant, so a Statement of Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's consideration.

For further information on the costs associated with the increased water demand, see Response to Comment 1-1. With regard to the comment that the SCAQMD should expand its analysis of water and wastewater use and handling, see also Responses to Comments 3-19, 3-29 and 3-31.

3-15 The comment does not include any information or data indicating that the use of SOx-reducing additives such as De-SOx at rates to meet the proposed BARCT levels would dilute the circulating cracking catalyst and adversely impact gasoline conversion (yield) within the FCCU[26]. The SCAQMD's own analysis also did not find that this would occur.

In 2008, the SCAQMD, WSPA and the refineries worked together and developed a testing protocol for SOx-reducing additives. The protocol was designed to demonstrate the performance and effectiveness of SOx-reducing additives to achieve a level of 10 ppmv or below. Only one out of six refineries elected to participate in the protocol. The participating refinery conducted short-term testing with SOx-reducing catalysts from September 2008 to November 2008. The SOx-reducing catalyst addition was approximately six percent to seven percent of the total catalyst addition, which was approximately 300 to 400 pounds per day. During this short term testing, the FCCU achieved a level of SOx below 10 ppmv without any negative effects on the yield of gasoline conversion. During the testing, in addition to the catalyst addition rate, the refinery carefully monitored numerous operating parameters (e.g., regenerator operating data such as burn mode, temperature, pressure, total air rate, coke burn rate; riser/reactor operating data such as feed preheat and riser temperature, pressure, FCCU feed rate, feed composition, conversion; and many other operating parameters) and no substantial problems with using the SOx-reducing additives were reported. Further, the refinery also conducted a source test for PM10 emissions and demonstrated that the FCCU continually met the requirements of Rule 1105.1, even with the increased use of SOx-reducing additives. Lastly, while the results of this study are confidential and cannot be disclosed in this response, the refinery reported to SCAQMD staff that they did not experience any substantial increase in loading to their SRU/TGU system during the three months of testing.

3-16 SCAQMD staff analyzed the likely SOx control technologies identified by the consultants as well as the refineries to meet BARCT and none suggested a "dry alternative." Dry gas scrubbers operating at 80 percent to 90 percent control efficiency were considered as BARCT for SOx in 1994. However, between 2008 and 2010, two consultants (ETS and NEC) expressed agreement that non-regenerative wet gas scrubbers can achieve from 1

[26] Letter from INTERCAT to SCAQMD, from Guido Aru, Director of Sales of INTERCAT to Dr. Laki Tisopulos, Assistant DEO of SCAQMD, October 10, 2010.

ppmv to 5 ppmv SOx outlet concentration (95 percent control efficiency or more from the 2005 emissions baseline) and thus, should be considered as BARCT. Based upon SCAQMD staff's and the consultants' evaluation of the dry gas scrubber technology, it is unlikely that it would achieve sufficient emission reductions to qualify as BARCT. While these two consultants recommended different types of WGSs, however, they both concurred that WGSs would be cost-effective and SCAQMD staff concurs with the consultants' recommendations. The two consultants both recommended keeping existing ESPs in place for particulate control and placing the wet gas scrubbers downstream of the ESPs. In addition, SCAQMD staff has worked with the refiners to demonstrate the effectiveness of enhanced usage of SOx-reducing additives, a dry technology, as a compliance option.

3-17 While SCAQMD staff acknowledges that the SOx oxidation catalysts have not yet been used at any of the refineries to reduce SOx from SRU/TGUs, the consultants (ETS/AEC) indicated that the catalysts have been used to capture SOx, destroy CO, VOC and PM10 from incinerators, heaters, turbines, and boilers. Therefore, the technology is transferrable to the SRU/TGU application. The consultants provided costs, cost-effectiveness and other parameters such as water usage and energy usage in Module 2. This information was incorporated in SCAQMD's costs and cost-effectiveness analyses for the SOx RECLAIM program and analyzed in the socioeconomic analysis.

In particular, the consultants have identified one facility (Facility A) that may consider employing the use of a proprietary catalytic gas treatment for their SRU/TGU called selective oxidation catalyst marketed by EmeraChem Power LLC as "ESx." The consultants also identified data relative to natural gas, electricity and catalyst consumption and this data was relied upon to determine air, energy and transportation impacts in the Draft PEA. As the ESx process does not utilize water, no water or wastewater impacts were identified. Thus, socioeconomic analysis has already considered costs of this type of control technology. Similarly, in addition to the information above on water and wastewater impacts, the Draft PEA already has analyzed impacts of these technologies on air quality, energy, and solid waste. For a summary of the environmental impacts for the SRU/TGU and ESx at Facility A, refer to Appendix B, Worksheet B-20.

3-18 Both consultants were in agreement that WGS is BARCT for coke calciner and it is cost-effective. NEC concurred with NEXIDEA on the BARCT selection stating, "*NEC concurs with the consultant's recommendation to use a Vendor D scrubber for emission control*."

NEC however thought that the contingency (35 percent) estimated by NEXIDEA was low. NEC suggested a 50 percent contingency instead. In addition, the facility had an issue with the location proposed by NEXIDEA. The facility operators indicated that this location is needed for truck access for coke loading/unloading. NEC reviewed the area and suggested to raise the WGS above the road. For this reason, the costs estimated by NEC were higher than those estimated by NEXIDEA. SCAQMD staff's calculation of cost-effectiveness for the coke calciner are based on NEC's recommendation as shown in Section 12.2, and 12.3 of Chapter 12 of Part 1 of the Staff Report, and is summarized in the following table:

	NEXIDEA	NEC
Capital Costs	$13.3 - $14.8 million	$45.7 million
Present Values	$21 - $23.4 million	$58.8 million
Cost Effectiveness	$9,902 per ton	$23,036 per ton

3-19 The comment states that the Draft PEA should consider a "reasonable, worst-case scenario" which would assume that no additional recycled water would be supplied to the RECLAIM facilities. California Public Resources Code §21159(a)(1) requires an analysis of *reasonably foreseeable* environmental impacts of the methods of compliance [emphasis added]. Further, CEQA Guidelines §15064(d) requires the lead agency to consider direct physical changes in the environment and *reasonably foreseeable* indirect physical changes in the environment which may be caused by the proposed project [emphasis added].

One reasonably foreseeable environmental impact to be expected from the proposed project is that some SOx control equipment such as WGSs could be installed and these devices are water-intensive. However, WGSs do not require the use of potable water in order to function. SCAQMD staff recognizes that the use of water-intensive equipment is a sensitive issue because California is in the midst of a drought. On February 27, 2009, Governor Schwarzenegger proclaimed a state of emergency regarding the drought and the availability and future sustainability of California's water resources. The proclamation directed all state government agencies to utilize their resources, implement a state emergency plan and provide assistance for people, communities and businesses impacted by the drought. The proclamation further requested that all urban water users immediately increase their water conservation activities in an effort to reduce their individual water use by 20 percent and the use of recycled water can be counted towards the progress in meeting this target.

Recognizing that there is a state goal for a 20 percent reduction in potable water consumption on a per capita basis, it is reasonable that any facility that currently has access to recycled water will choose to tie into their existing recycled water pipeline to operate their WGS (or any other water-intensive SOx controls that do not require potable water) instead of only installing a connection to their potable water supply and increasing their use of potable water at the facility. This is especially true because, according to LADWP (see next paragraph), LADWP is providing competitive pricing to its customers to incentivize the use of recycled water. For these reasons, the hydrology analysis in the Draft PEA considers the use of recycled water for those facilities that currently have access to it.

In addition, representatives from both the LADWP and WBMWD have provided detailed information about the availability of future access to recycled water to specific facilities that may also be affected by the SOx RECLAIM project, but do not have access at present. Further, these representatives have assured SCAQMD staff that there is currently an over-abundance of reliable recycled water ready for use. The Draft PEA considers what the potable water demand would be if future recycled water will be available to these facilities. However, the Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. The

conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available.

3-20 Subsequent to the release of the January 2010 Staff Report, manufacturers of SOx-reducing additives such as De-SOx catalyst provided SCAQMD staff with data indicating that 5 ppmv SOx level is achievable for FCCUs. On this basis, BARCT at 5 ppmv may be met by using SOx-reducing additives or WGSs. The potential environmental effects of using SOx-reducing additives in lieu of WGSs for FCCUs have been analyzed in the Draft PEA and have been shown to have less impacts than WGSs. The analysis specific to the use of SOx reducing additives can be found in Appendix B, Worksheet B-31.

3-21 The first set of consultants explored several measures that were specific to fuel gas treatment. Their purpose was to find controls that would lower the fuel gas sulfur that is fed to the refinery boilers and heaters. A 40 ppmv sulfur concentration in the refinery fuel gas has been justified as technologically and economically feasible with SCAQMD Rule 431.1. SCAQMD's proposal does not assume a new BARCT standard for refinery boilers and heaters. In fact, the 40 ppmv fuel sulfur concentration is an existing BARCT standard that was adopted in the May 4, 1990 amendments to SCAQMD Rule 431.1 – Sulfur Content of Gaseous Fuels, and became effective on May 4, 1992; it is still applicable today. However, with the adoption of the RECLAIM program in April 1993, the command-and-control rules, like Rule 431.1, were subsumed, giving the refineries flexibility in complying with this BARCT standard. Over the past 18 years since going into effect, several refineries have avoided meeting the 40 ppmv fuel sulfur concentration BARCT standard under RECLAIM. To the extent that these refineries have avoided meeting that limit because of costs, SCAQMD staff has determined that the proposed shave can be readily met without complying with the 40 ppmv fuel sulfur concentration limit. WSPA's proposal listing various control strategies supports SCAQMD staff's position. As a result, it is not reasonably foreseeable that refiners who avoided complying with the 40 ppmv fuel sulfur concentration limit due to costs would be required to do so now as a result of the proposed shave. Nevertheless, SCAQMD staff has analyzed the potential environmental impacts of complying with the 40 ppmv fuel sulfur concentration limit in the Draft PEA.

3-22 Although not part of SCAQMD's proposal for new BARCT because it is existing BARCT pursuant to Rule 431.1 as explained in Response to Comment 3-21, the consultant ETS/AEC conducted site-specific analyses for fuel gas treatment, and found several possible measures that were cost effective. These are summarized in Module 2 of the consultant's analyses. For this reason, an analysis of the environmental effects associated with fuel gas treatment in the Draft PEA has been included because the consultants' reports indicated that some of the affected facilities may choose to focus on improving SOx emissions from their refinery boilers and heaters in lieu of other equipment. The analysis specific to the refinery boilers and heaters source category identifies the specific facilities that may benefit from SOx reductions. This analysis can be found in Appendix B, Worksheet B-19.

3-23 Nothing in the proposed amended rule would prohibit the use of a "dry" alternative. However, as the commenter pointed out, the CEQA analysis looked at a worst-case scenario of using WGSs, which have a greater water impact. See also Response to Comment 3-16.

3-24 SCAQMD staff would be interested in obtaining more information on the basis for selecting perpetuity credits instead of single-year credits. It should be noted that in a given year, the perpetuity credits would tend to be less expensive than single-year credits because even though the value of perpetuity credits represent an infinite block of emission reductions, on an annualized basis, the value is discounted when compared to a single-year credit. Consequently, the single-year credit would be more a conservative criterion with respect to a RTC trading threshold. Nevertheless, as suggested by the SCAQMD's Executive Officer at the October 14, 2010 Refinery Committee meeting, SCAQMD staff is open to proposals for other trigger thresholds for subparagraphs (f)(1)(M) and (f)(1)(N) in Rule 2002.

3-25 The analysis of the proposed project, which takes into consideration the compliance schedule, demonstrates that the emission reductions as listed in the schedule in the proposed amended rule are achievable while providing a means for giving the affected facilities sufficient time to install the required SOx reducing control equipment. Because facilities will have the flexibility under the RECLAIM program to install air pollution control equipment, change method of operations, and/or purchase RTCs to meet BARCT levels, the analysis in the Draft PEA for the proposed project and each of the alternatives is based on the conservative assumption that multiple projects could be under construction at any one time, regardless of the amount and the year when the RTC reductions would occur. So even if a less aggressive RTC reduction was employed or if more facilities wait until later to implement physical changes to reduce their SOx emissions, the worst-case environmental impacts on a peak daily basis will likely remain unchanged.

3-26 Although the current SOx RTC market may be "thinly traded" as asserted by the commenter, this is not the result of unavailability of SOx RTCs. As noted in Response to Comment 2-26, the surplus SOx RTC pool had approximately 1.73 tons per day of unused RTCs in 2005, and 2.55 tons per day of unused RTCs in 2008. Based on currently available information, SCAQMD staff has concluded that with its proposed shave there should be an adequate supply of RTCs to ensure market stability. The actual availability in the future cannot be substantiated by fact. CEQA recognizes this by stating that a CEQA document "…necessarily involves some degree of forecasting. While foreseeing the unforeseeable is not possible, an agency must use its best efforts to find out and disclose all that it reasonably can." [CEQA Guidelines §15144] Consistent with CEQA, SCAQMD staff has used the best information currently available to project future RTC availability and market responses to project RTC availability (see the Socioeconomic Report for the proposed project). In the event RTC prices spike to a level of concern, a "safety valve," similar to a component in the NOx RECLAIM program, has been added to the SOx RECLAIM program. This "safety valve" sets aside a portion of the RTCs called non-tradable/non-usable RTCs from 2015 to 2019. In a scenario where SOx RTC prices exceed $50,000 per ton, SCAQMD staff will be required to report to the Governing Board at a public hearing. The Governing Board will decide whether to convert any portion of the non-tradable/non-usable RTCs to tradable/usable RTCs, and how much to convert. This approach is expected to help the market regain its balance should the price of RTCs increase above $50,000 per ton because it would increase the RTCs in the market. The "safety valve" provision added to the NOx RECLAIM rules helped stabilize the NOx trading market and there is no reason to believe that it would not have the same effect on the SOx market in the event of price spikes.

3-27 SCAQMD staff recognizes the fact that the design and layout of equipment during construction and installation are key parameters that rely on the appropriate and available plot space. Two sets of consultants were hired specifically to address this issue and made assessments of the available plot space for each control technology measure, so it is incorrect to say that the consultants did "not give adequate weight" to plot space considerations. The consultants based their findings on site visits; their collective experience in refinery technology design, construction, and installation; and on input that was elicited from the affected facilities on several occasions. The consultants' final recommendations identify BARCT that can be installed within the plot space of each individual affected facility based on an analysis of all of the above factors. The consultant reports can be found online at the following URL: http://www.aqmd.gov/rules/proposed.html#RegulationXX.

The commenter notes also, "If the District's assumptions on layout are incorrect, it could mean that a lot more construction must be done which will have greater impacts." First, the comment does not identify which assumptions may be inappropriate. Second, the assumptions with regard to constructing and analyzing impacts from installation of control technologies are clearly laid out in Chapter 4 of the PEA, but the commenter does not provide suggestions for different assumptions. Third, information on construction activities was solicited from affected facility representatives. Finally, the assumptions used in the PEA are considered to be "worst-case" assumptions based on a number of factors including engineering time, time to obtain control equipment and associated materials, availability of appropriately trained construction crews that are able to install the necessary control equipment, etc.

3-28 As discussed in Response to Comment 3-27, the consultants reached their conclusions regarding the availability of plot space and assumptions used in the analysis, the consultants reached their conclusions after visits to the affected facilities and soliciting and receiving input from the affected facility operators. This is why the PEA analyzed different control technologies for each facility. In addition, the comment does not provide any information with regard to why the consultant analysis regarding plot space is inaccurate nor does it provide any recommendations for alternative assumptions or analyses.

3-29 As noted in the PEA, one of the SCAQMD's significance criteria for hydrology/water quality is whether or not the existing water supply has the capacity to meet the increased demands of the proposed project. SCAQMD staff contacted the water purveyors for each of the affected facilities and they have confirmed that that they would be able to supply the needed amount of potable water for the proposed project[27]. In addition, for those facilities that currently have access to recycled water (i.e., Facilities A, B, and D), the applicable water purveyor indicated that it would also be able to supply additional recycled water to accommodate the water demand for the proposed project. Lastly, for those facilities that may have access to future supplies of recycled water (i.e., Facilities C, E, and F), the

[27] Facilities A, B, C, D, E and F: West Basin Municipal Water District, email from Uzi Daniel, February 17, 2010.
Facilities C, E, and F: LADWP, letter from James McDaniel, August 16, 2010.
Facility H: Long Beach Water Department, conversation with Chris Pincherli, August 13, 2010.
Facility I: City of Vernon, email from Scott Rigg, July 28, 2010.
Facility J: No water purveyor; all water is supplied from on-site wells and this facility has unlimited pumping rights.

applicable water purveyor indicated that it would also be able to supply either potable water or recycled water for the proposed project.

The Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Since the HRRWPP has not yet been constructed and the affected facilities have not tied into the system, the PEA does not assume that recycled water will be available. For that reason, the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For these reasons, potable water demand was found to be significant, so a Statement of Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's consideration.

Regarding the infrastructure to increase current supplies of recycled water to Facilities A, B and D as well as to provide future supplies of recycled water to Facilities C, E, and F, representatives from both the LADWP and the WBMWD have assured SCAQMD staff of the following:

1) The existing infrastructure that currently provides recycled water to Facilities A, B and D can handle the proposed increase of additional recycled water to supply the proposed project.
2) The new infrastructure that is currently under construction pursuant to the HRRWPP will provide Facilities C, E, and F with new access to recycled water. The HRRWPP is expected to be completed by Summer 2013. Should any of these facilities install water-based SOx control equipment prior to completion of the HRRWPP, potable water will be supplied. When the HRRWPP is completed, each facility can tie-in to the recycled water pipeline.

The physical and economic feasibility of recycled water pipeline infrastructure has already been evaluated in the Final EIR for the HRRWPP. The HRRWPP would occur regardless of the SCAQMD's proposed project to amend the SOx RECLAIM program. Thus, the Draft PEA need not evaluate the impacts that would occur pursuant to the HRRWPP. See also Response to Comment 3-19.

3-30 From a construction point of view, the installation of a WGS, for example, is a complex process. If a facility operator chooses to install a WGS, the consultants' reports estimate that 18 months would be needed for pre-construction/advance planning activities such as engineering analysis of the affected equipment, engineering design of the potential control equipment, contracting with a vendor, securing financing, ordering and purchasing the equipment, obtaining permits and clearances, and lining up contractors and workers. Further, to physically build a WGS, the consultants' reports indicated that an additional 18 months would be needed. The Draft PEA considers the overlapping construction of building four WGSs within the same 18-month period as a worst-case scenario. This overlap could occur anytime between the date of adoption (scheduled for November 5, 2010) and full implementation (January 1, 2019). However, as a practical matter, even if a facility starts the planning and engineering process immediately if the proposed project is adopted in November 2010 (the currently scheduled public hearing date) to design a WGS installation (and some are in the very early pre-planning stages), construction is not

expected to occur sooner than 2012. For these reasons, the Draft PEA considers any 18-month window between January 1, 2012 and January 1, 2019 (a span of seven years) when facilities could undergo construction activities. Further, based on the practicalities of engineering and constructing applicable control equipment a shorter installation period, such as three years as suggested in the comment, is unrealistic.

3-31 As previously mentioned in Response to Comment 3-19, the Draft PEA analyzes the worst-case potable water demand for the proposed project which was based on data provided by the consultants, the operators of the affected facilities, and the water purveyors. The analysis also takes into account the drought in California, the water conservation measures and the use of recycled water to help meet the water conservation measures. The conclusion of the analysis is that the estimated amounts do not make the proposed project infeasible. As mentioned in Response to Comment 3-29, the water purveyors for each of the affected facilities have confirmed that both potable and recycled water is available and will be supplied to any affected facility that requests it, in amounts necessary to carry out the project.

While it is true that the California legislature has proposed Assembly Bill (AB) 49 – Water Efficiency and Senate Bill (SB) 261 – Urban Water Efficiency, which will require a 10 percent reduction of urban water use by 2015 and 20 percent by 2020, neither of these bills has been adopted by the full legislature. On January 27, 2010, AB 49 was moved to the inactive file[28]. On August 27, 2009, a hearing was set for SB 261 and then canceled[29]. These are the last times any actions were taken on these bills.

In any case, these proposed bills and the water conservation measures share a common concept, which is to allow the use of recycled water to count towards the progress in meeting these targets. Thus, if an affected facility proposes to increase its water use as a result of the proposed project by installing water-based SOx controls, and uses recycled water to satisfy the water demand, the increased use of recycled water would not cause the facility to incur: 1) voluntary reductions; 2) mandatory restrictions during a local emergency; 3) drought rates, surcharges and fines; 4) limits on the new construction subject to water efficient landscaping; or, 5) mandatory conservation. Further, the HRRWPP project is one mechanism designed specifically to convert all of the refineries from potable water to recycled water and the feasibility and cost-effectiveness of this goal was analyzed in the Final EIR for the HRRWPP.

While the preparation of the Draft PEA and in particular, the hydrology analysis, is dependent upon information from the certified Final EIR for the HRRWPP project as it relates to the affected facilities for the SOx RECLAIM project, CEQA Guidelines §15148 requires the document to be cited, but not included in the Draft PEA. Thus, there is no requirement to incorporate or re-analyze in the Draft PEA what was already analyzed and concluded in the Final EIR for the HRRWPP as being cost-effective and feasible with regard to the use of recycled water. The Final EIR for the HRRWPP clearly states and representatives from the LADWP and WBMWD (the project's sponsors) agree that recycled water will be available to the specified facilities (see also Response to Comment 3-29).

[28] http://www.leginfo.ca.gov/pub/09-10/bill/asm/ab_0001-0050/ab_49_bill_20101006_status.html
[29] http://www.leginfo.ca.gov/pub/09-10/bill/sen/sb_0251-0300/sb_261_bill_20090831_status.html

The commenter's statement that the potable water impacts could be less than significant with mitigation is not complete, and is taken out of context. The conclusion states that the overall water demand will not be completely mitigated, even with the use of recycled water. The conclusion can be found on page 4-84 of the Draft PEA. It is important to note that even if mitigation measures cannot fully reduce the impacts to below significance, not being able to fully mitigate the impact would not make the mitigation measure infeasible or unreasonable.

With regard to the remark that the SCAQMD has incorrectly implied that each facility has the ability to obtain written declarations that recycled water is not available pursuant to mitigation measures GHG-2 and HWQ-2, the commenter does not explain why the facilities would not be able to obtain such a declaration. This remark is inconsistent with discussions SCAQMD staff has had with representatives from both the LADWP and WBMWD. Both of these water purveyors have indicated that their staff has met with each facility operator (i.e., those with current supplies of recycled water as well as those with future access to recycled water) as part of a series of on-going negotiations and discussions about their plans to convert from potable water to recycled water. Based on this understanding, there should be no barrier to facility operators obtaining a written declaration from their water purveyor about the status of their current or potential future recycled water supplies. Even if the commenter were correct that the facilities could not obtain such a declaration, this would not change the conclusion that water demand impacts remain significant even after mitigation, but that overriding considerations, nevertheless justify adoption of the proposed project.

It is important to note, however, that the Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Since the HRRWPP has not yet been constructed and the affected facilities have not tied into the system, the PEA does not assume that recycled water will be available. For that reason, the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For these reasons, potable water demand was found to be significant, so Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's approval.

3-32 Two potential control options have been identified for FCCUs: WGSs and SOx-reducing additives. SCAQMD staff believes that 5 ppmv should be the BARCT level for FCCUs based on the performance of an existing WGS installed and operated in the District since 2008. Therefore, the actual emission reductions from the 2005 baseline should be estimated based on a BARCT level of 5 ppmv, and the emission reductions for the two options analyzed in the Draft PEA should both be equal to 2.88 tons per day for FCCUs. SCAQMD staff acknowledges that the 5 ppmv has not yet been fully demonstrated in practice for the SOx-reducing additives. However, short-term testing with a local refinery and multiple discussions with the manufacturers of SOx-reducing additives who have presented SCAQMD staff with actual testing results indicated that the use of SOx-reducing additives can potentially achieve 5 ppmv SOx on a long-term basis. Further, the use of

SOx-reducing additives is not expected to incur any upfront additional capital costs like WGSs. While the annual operating costs are likely to be high for SOx-reducing additives when compared to WGSs, the water demand will be less with SOx-reducing additives. Other environmental impacts and differences between the two technologies are analyzed in the Draft PEA. See also Response to Comment 3-20.

In addition to the fact that both WGSs and SOx-reducing additives may be considered BARCT, the analysis of these technologies also relies on the concept of analyzing maximum impacts that could be created by the technologies to ensure that all potential adverse impacts that may be generated by the proposed project are identified and disclosed to the public. Further, it is important to remember that the PEA is a program level analysis that shows the options a facility may choose to comply with the proposed requirements. The RECLAIM program does not mandate that any particular technology be adopted by facility. For this reason, the analysis is based on those technologies that would allow the facility to comply with the proposed project, while generating the maximum adverse impacts as indicated above.

3-33 The proposed RTC shave values are from Table 13-1 of the Staff Report. They are the RTC reductions in Year 2019 with a 10 percent compliance margin. Although refinery heaters and boilers are not part of the proposed project, they are a potential source of cost-effective SOx reductions. A facility operator may seek additional reductions from this source category if it chooses to. The benefit of analyzing the potential environmental impacts from this source category is that if a facility operator chooses to install controls for refinery heaters and boilers in the future, this PEA may be used for those projects. The SCAQMD encourages the substitution of more cost-effective controls on a site-by-site basis. A facility operator may choose to install cost-effective controls for refinery boilers and heaters and, if those controls achieve further reductions that those specified as Tier 1, then those reductions can be used to displace the reductions from other equipment.

3-34 With regard to the assumptions and analysis associated with the current and future use recycled water as part of implementing the proposed project, see Responses to Comments 3-19, 3-29, and 3-31.

3-35 While it is true that no new BARCT is being proposed for the refinery boilers and heaters source category, the 40 ppm SOx limit was not explicitly included in the previous versions of the SOx RECLAIM rules and as such, is now included in the proposal (see Table 4 in PAR 2002). As explained in Response to Comment 3-22, an analysis of the environmental effects associated with fuel gas treatment in the Draft PEA has been included because the consultants' reports indicated that some of the affected facilities may choose to focus on improving SOx emissions from their refinery boilers and heaters in lieu of other equipment and that choice may have direct and indirect environmental impacts.

3-36 See Responses to Comments 3-20 and 3-32.

3-37 For a discussion about the assumptions associated with timing of construction, see Response to Comment 3-30.

3-38 The analysis in the Draft PEA considers the proposed project and three alternatives. A summary of the environmental impacts can be found in Table 5-60 and shows a side-by-

side comparison of each environmental topic. The comment states that Alternatives B and C "would cause significantly fewer environmental impacts… particularly associated with water use and GHG impacts" than the proposed project. Although the analysis of GHG impacts estimated for Alternative B in Chapter 5 of the PEA are less than significant, the GHG impacts for Alternative C exceed the 10,000 MTCOeq/yr significance threshold.

Similarly for total water demand, neither the proposed project nor any of the alternatives exceed the total water significance threshold. Further, the proposed project and Alternative C have identical, significant potable water demand impacts and only Alternative B has less than significant potable water demand impacts. The comment that there are significantly less impacts from Alternative C compared to the proposed project is inconsistent with analysis of impacts from the project alternatives in Chapter 5 of the PEA. While it is true that Alternative B has less impacts overall when compared to the proposed project, it also achieves the least amount of SOx emission reductions. As a result, the proposed project was preferred over the project alternatives because, even though the proposed project has the potential generate more or more significant adverse environmental impacts, it is more effective at achieving the project objectives than all alternatives evaluated.

3-39 Because there are SOx controls that need water for operation and because the HRRWPP project has identified several facilities that have current or may have future access to recycled water, mitigation measure GHG-2 was designed to work in cooperation with mitigation measure GHG-1 as a backstop to make sure that the water purveyor vouches for the recycled water status at a given facility. In the event that recycled water cannot be delivered to a given facility and potable water needs to be used instead, there will be no reductions in GHG emissions. However, if recycled water is used, there will be less GHGs generated than if potable water was used due to less energy needs for transport. All affected water purveyors have participated in the CEQA process for the proposed project, all have received copies of the PEA and none has expressed concern about this mitigation measure.

3-40 Currently there are two feasible GHG mitigation measures identified in the Draft PEA that are designed to work together to reduce GHG emissions by utilizing recycled water in lieu of potable water, if available. These mitigation measures do not rely on AB 32 projects serving as GHG mitigation measures. AB 32 is mentioned in the Draft PEA as part of the mitigation measure discussion because it is an ongoing process under development by CARB that may result in further GHG emission reductions. While there is nothing in CARB's adopted "early action measures" or CARB's GHG reduction measures that specifically apply to the proposed project as of this writing, CARB has not yet adopted its GHG reduction cap and trade program. When adopted, it is expected to apply to projects that will need to receive permits, including any projects that may occur as a result of amending the SOx RECLAIM program. The purpose of the discussion of AB 32 is to indicate that there are no additional feasible GHG reduction measures that the SCAQMD could adopt that could mitigate impacts from the proposed project, able to go beyond AB 32 requirements.

With regard to applicability of GHG BACT via EPA's Tailoring Rule, the SCAQMD would begin to require GHG BACT for sources already subject to PSD and having a GHG increase of 75,000 MTCO2eq/yr or more, effective January 2, 2011. However, the analysis in the Draft PEA has demonstrated that on an individual facility basis, no facility exceeds

the 10,000 MTCO2eq/yr threshold and for the project as a whole, let alone individual modifications, the GHG emissions do not exceed 75,000 MTCO2eq/yr. Thus, GHG BACT would not apply to the proposed project or any permit action thereafter.

With regard to applicability of NSR and PSD, see Response to Comment 3-9. Lastly, with regard to the comparison of environmental impacts between the proposed project and Alternatives B and C, see Responses to Comments 3-6, 3-7 and 3-38.

3-41 There is a direct relationship between CEQA and GHG BACT as CEQA requires all feasible measures, and GHG BACT is based on what is achievable in practice. Therefore, if GHG BACT can be achieved in practice, then it may also be considered as feasible under CEQA. The purpose of this discussion was to indicate that no additional GHG reduction measures beyond GHG BACT could feasibly be imposed to mitigate impacts from the proposed project.

3-42 The comment states that the Draft PEA did not account for the energy needed to pump potable water to the affected facilities. The analysis in the Draft PEA is based on energy demand from using potable water and does not take any credit for any energy reductions that may occur from using recycled water instead.

3-43 The water purveyors for each affected facility have indicated that, from their perspectives, the proposed increases in water are relatively small. Further, as mentioned in Responses to Comments 3-14, 3-29 and 3-31, the water purveyors have indicated that they can supply the water demand, whether it is for potable water, recycled water or a combination of the two. None of the water purveyor representatives have indicated that there are any regulations in place that would be impediments for them to supply the affected facilities with potable water, if requested, by the facility operators.

3-44 With regard to the appropriateness and feasibility of mitigation measure GHG-2, see Response to Comment 3-39. With regard to the Draft PEA identifying feasible mitigation measures, see Responses to Comments 3-9 and 3-31.

3-45 The comment states that the most likely scenario to analyze would be that there will be no additional supplies of recycled water available to the refineries. This position is not supported by the conclusions in the HRRWPP project and the water purveyor's affirmations, as discussed in Responses to Comments 3-14, 3-29, and 3-31, that both potable water and recycled water will be fully available to the affected facilities. Also, as mentioned in Response to Comment 3-43, none of the water purveyor representatives have indicated that there are any regulations in place that would be impediments for them to supply the affected facilities with potable water, if requested, by the facility operators.

The Draft PEA also considers what the potable water demand would be in the event that future recycled water will not be available, despite the fact that the HRRWPP project is currently under construction and it is reasonably foreseeable that at completion of construction, future recycled water will be made available to certain facilities. Since the HRRWPP has not yet been constructed and the affected facilities have not tied into the system, the PEA does not assume that recycled water will be available. For that reason, the conclusion of significance in the Draft PEA for potable water demand is based on the more conservative approach that future supplies of recycled water may not be available. For

these reasons, potable water demand was found to be significant, so a Statement of Findings (CEQA Guidelines §15091) and a Statement of Overriding Considerations (CEQA Guidelines §15093) will be prepared for the Governing Board's consideration.

3-46 With regard to the Draft PEA analyzing the circumstance of no future increases in recycled water, see Response to Comment 3-19. With regard to the comment that compliance with mitigation measure GHG-2 is out of control of the facility operator and as such it cannot be imposed on a facility, see Response to Comment 3-31.

3-47 While all of the details associated with the proposed project and each of the alternatives are not fully specified in Table 5-1 because it is intended as tool to provide a brief overview or summary, a very detailed description of each component of the proposed project and each alternative is fully described throughout Chapter 5. With regard to how the same emission reductions are expected to be achieved for both options of Alternative C, see Responses to Comments 3-20 and 3-32.

3-48 See Response to Comment 3-33.

3-49 The project description for Alternative C on page 5-13 does not include the refinery boilers/heaters source category because the proposed project does not establish a new BARCT level for refinery boilers/heaters. However, cost-effective emission reductions in the amount of 0.85 ton per day are potentially available from future retrofits in this source category and the environmental impacts from such controls are evaluated in this analysis but the potential emission reductions are excluded from the proposed RTC shave.

3-50 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that both options of the proposed project are equivalent for natural gas reductions. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Energy Impacts Significant?" row: 1) in the "Proposed Project - Option 1" column: *The reduction in the use of natural gas is equivalent to the proposed project – Option 2*; and, b) in the "Proposed Project - Option 2" column: *The reduction in the use of natural gas is equivalent to the proposed project – Option 1*.

The commenter is correct that the natural gas reductions under both options of Alternative C are approximately eight times greater than the proposed project.

3-51 With regard to why Alternative C is not preferred when compared to the proposed project, see Response to Comment 3-7.

3-52 SCAQMD staff has conducted a sensitivity analysis to assess the future health impacts associated with meeting the PM 2.5 standard in 2020. A health impacts model was run to assess the incremental changes in PM levels as a function of SOx emissions. The analysis showed that reducing PM levels resulted in reductions in premature deaths and chronic bronchitis resulting from reductions in annual average PM2.5 concentrations; and reductions in respiratory and cardiovascular hospital admissions, emergency room visits, asthma symptom days, acute respiratory symptom days, and non-fatal heart attacks. The report on the 2007 AQMP Socioeconomic Analysis can be extrapolated to reflect the health impacts associated with PM as a result of SOx emissions. This was an emissions-based

linear model to estimate the air quality and health impacts in 2020. The studies found that there are health benefits with SOx emission reductions beyond what is specified in the AQMP in the effort to meet the future PM 2.5 standards. Thus, the statement on page 5-20 of the Draft PEA correctly characterizes the potential emission reductions and health benefits of Alternative C relative to those of the proposed project.

3-53 .Regarding analyzing the project without assuming new or increased access to potable water, see Responses to Comments 3-29 and 3-31.

3-54 In order to achieve the air quality benefits reflected by the proposed BARCT standards, it is important that surplus unused RTCs are reduced. The shave methodology used by SCAQMD staff does account for anticipated future growth and provides a compliance range that is within 10 percent of the shave methodologies analyzed prior to RECLAIM amendments. Thus, the shave reductions of the proposed project are designed to meet the 2007 AQMP targets as well as future attainment standards for PM 2.5. The Draft PEA analyzes the potential effects of what facility operators may do to implement the proposed project.

3-55 See Response to Comment 3-52.

3-56 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that the use of NaOH for Alternative B is less than both options of the proposed project. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Air Quality Impacts Significant?" row in the "Alternative B: AQMP" column, third bullet: *Less than significant for TACS use (NaOH) during operations, and less than the proposed project for both Options 1 and 2*.

3-57 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that GHG emissions for Alternative C – Option 1 are less than the proposed project – Option 1 but greater than the proposed project – Option 2. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Air Quality Impacts Significant?" row in the "Alternative C - Option 1" column, second bullet: *Significant for GHGs but less than the proposed project -Option 1 and more greater than the proposed project - Option 2.*

3-58 The commenter has identified an inconsistency in the Table 5-2, which is also in Table 1-4. Review of the text in the body of the document and the calculations in Appendix B confirms that the number of daily truck trips for construction is the same for both options of the proposed project (e.g., 700) and the number of daily truck trips for operation are slightly more for the proposed project – Option 1. As such, both Table 1-4 and Table 5-2 have been corrected to state the following in the "Transportation & Traffic Impacts Significant?" row: 1) in the "Proposed Project - Option 1" column: *Less than significant, but equivalent to the proposed project – Option 2 for construction and more than the proposed project – Option 2 for operation*; and, 2) in the "Proposed Project - Option 2" column: *Less than significant, but equivalent to the proposed project – Option 1 for construction and less than the proposed project – Option 2 for operation.*

3-59 The commenter has identified a typo in the last paragraph on page 5-20. The typo has been corrected to reflect that eight WGSs plus two DGSs for a total of 10 add-on controls were analyzed Alternative C – Option 1.

3-60 The commenter has identified some typos on page 5-34 and Table 5-25. The numbers have been updated and are now consistent with each other.

3-61 The commenter has identified a typo relative to the amount of water needed for construction for both options of Alternative C. The amount of plot space that would be affected by Alternative C is less than the proposed project. This means that the amount of water needed to control the fugitive dust should be about the same or less for Alternative C than the proposed project because the amount of soil that can be disturbed in one day, is physically limited by the amount that construction equipment such as a backhoe can do. For these reasons, the amount of water that may be applied to minimize fugitive dust for Alternative C has been adjusted to be the same as the proposed project during construction (i.e., 52,272 gal/day).

3-62 The commenter has identified a typo relative to Footnote 12 in Table 1-3. The reference has been corrected to reflect Footnote 14 instead.

Back to Agenda

BOARD MEETING DATE: November 5, 2010 AGENDA NO. 38

PROPOSAL: Amend Rule 1175 – Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products

SYNOPSIS: Proposed Amended Rule 1175 will address the concerns expressed by the U.S. EPA in their disapproval of the September 2007 amendment. As requested by the U.S. EPA, the proposed amended rule will require source testing to demonstrate compliance, require all operational parameters necessary for compliance to be contained in a federally enforceable permit and recordkeeping to verify operational techniques and parameters. The proposed rule will also clarify the prohibition of use for chlorofluorocarbons to be consistent with U.S. EPA Significant New Alternatives Policy Program, correct typographical errors and make minor clarifications and editorial corrections to the rule. The proposed changes are administrative in nature and are not expected to impact emissions or costs.

COMMITTEE: Stationary Source, September 24, 2010, Reviewed

RECOMMENDED ACTIONS:
Adopt the Resolution:

1. Certifying the Notice of Exemption for the proposed amendments to Rule 1175 – Control of Emissions from the Manufacture of Cellular (Foam) Products; and

2. Adopting Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products.

Barry R. Wallerstein, D.Env.
Executive Officer

EC:LT: NB:DO:MM

Background
Rule 1175 was adopted November 3, 1989 and has since been amended three times with the last amendment on September 7, 2007. The rule prohibits the use of chlorofluorocarbons (CFCs), Volatile Organic Compounds (VOCs) and methylene chloride in polymeric cellular foam product operations except for expandable polystyrene molding and extrudable polystyrene foam operations. The rule controls VOC emissions of expandable polystyrene molding operations and extrudable polystyrene foam operations by either requiring control devices to capture VOC emissions or by limiting emissions to 2.4 pounds of VOC emitted per 100 pounds of product produced.

The September 7, 2007 rule amendment provides block foam manufacturers with an alternative compliance option that allowed for equivalent emissions collection and control by over-controlling the manufacturing emissions, in lieu of controlling their less cost-effective block storage areas. On May 10, 2010, as published in the Federal Register [FR Doc 2010-109121], U.S. EPA announced their disapproval to the amendment on the grounds that the rule did not explicitly require source testing to demonstrate compliance. Although source testing requirements are currently reflected in the individual permits held by facilities subject to the rule, the proposed amendments will address the rule deficiencies identified by U.S. EPA by explicitly stating source testing requirements and other improvements into the rule.

Affected Facilities
The facilities subject to the proposed rule include polystyrene foam product manufacturing, urethane and other foam product manufacturing. Such facilities manufacture food containers, ice chests, insulation, packaging and other foam products. Currently there are an estimated 21 facilities subject to the proposed rule.

Public Process
On May 10, 2010, U.S. EPA announced their disapproval to the amendment. A public workshop was held on September 7, 2010.

Proposal
As requested by the U.S. EPA, the proposed amended rule will require source testing to demonstrate compliance, require all operational parameters to be contained in a federally enforceable permit and include record keeping to verify operational techniques and parameters.

Sources subject to Rule 1175 that utilize an approved emission control device to comply with the rule are required to obtain a federally enforceable permit from the District. At the time of permit issuance, the Executive Officer, in writing, will impose specific permit conditions reflecting the necessary parameters needed to achieve this level of control. The specific parameters may include, but are not limited to, establishing

specific temperatures and pressure limits for aging rooms, establishing volumetric flow rates into a control device and requiring a minimum operating temperature for the control device. Failure to maintain the control device in good operating condition, including conditions imposed by the Executive Officer, will be considered a violation of Rule 1175.

Furthermore, facilities utilizing control equipment to comply with the provisions of the proposed rule will be required to conduct source testing, approved in writing by the Executive Officer, to demonstrate the collection and control efficiency. Such testing is routinely required as part of the permitting process.

The prohibition of using methylene chloride and CFCs has been relocated to subdivision (d) to clarify that the prohibition applies to all polyurethane operations subject to the rule including expandable polystyrene molding operations and extruded polystyrene foam operations. All CFCs used in operations subject to Rule 1175 are prohibited unless specifically approved as acceptable alternatives under 40 CFR Part 82 Subpart G – Significant New Alternatives Policy (SNAP) Program. This will provide consistency between Rule 1175 and federal requirements. At this time the only use of CFCs approved in foam products is HCFC-141b for space vehicle, nuclear, defense and research and development for foreign customers (see Appendix M to Subpart G—Unacceptable Substitutes Listed in the September 30, 2004 Final Rule, Effective November 29, 2004).

Records of operations and emission control system parameters shall be maintained for five years to maintain consistency with Title V permit requirements.

The proposed rule will also make clarifications to the definitions and applicability of the rule, correct typographical errors and make minor editorial corrections to the rule.

The proposed changes are administrative in nature and are not expected to impact emissions or costs.

Key Issues

A few key issues have been brought to staff's attention during the rule making period. The most notable issues and their resolutions are summarized below:

ISSUE: Clarify that Rule 1175 is not in conflict with Federal requirements on prohibited foam blowing agents.

RESPONSE: The proposed rule has been modified to prohibit the use of all CFCs in foam operations except those specifically approved under the SNAP program. This will provide consistency between Rule 1175 and the federal requirements.

ISSUE: The alternative compliance option under (c)(5) should be available to shape molding operations. Shape molders have similar issues as the block molders do when it comes to product density, inability to construct 48-hour controlled enclosures due to leased property and limited space and the need to process some higher pentane material while processing mostly low-to-mid-range pentane material.

RESPONSE: The data currently provided to demonstrate equivalence is insufficient to make a determination to include shape molding operations under the alternative compliance option. Further testing is necessary to establish the collection efficiency of the control equipment and emissions lost during the initial 48 hours of storage. Staff will continue to work with interested parties to determine if the alternative compliance option can be made available to shape molding operations.

Emission Reductions and Cost Effectiveness Determination

The proposed changes are administrative in nature and are not expected to impact emissions or costs.

AQMP and Legal Mandates

Proposed Amended Rule (PAR) 1175 will address the concerns expressed by the U.S. EPA in their disapproval of the September 2007 amendment. While the proposed amendments do not result in additional emission reductions, the amendments are consistent with AQMP objectives. The proposed amendment does contain source testing, permitting and record keeping requirements; however, these demonstration and documentation activities are routinely required as part of the permitting process.

California Environmental Quality Act

Staff has reviewed the proposed amendments to Rule 1175 – Control of Emissions from the Manufacture of Cellular (Foam) Products, pursuant to CEQA Guidelines § 15002(k)(1) - Three Step Process, and has determined that the proposed amendments are exempt from CEQA pursuant to CEQA Guidelines § 15061(b)(3) – Review for Exemption. The proposed amendments are covered by the general rule that CEQA applies only to projects which may have a significant effect on the environment. Staff has reviewed the proposed amendments and has determined that it can be seen with certainty that there is no possibility that proposed amendments to Rule 1175 will have a significant impact on air quality or other environmental areas. Therefore, the proposed project is exempt from CEQA. If approved by the Governing Board, a Notice of Exemption (NOE) will be prepared for the proposed project pursuant to CEQA Guidelines §15062 – Notice of Exemption, and mailed to the county clerks of Los Angeles, Orange, Riverside, and San Bernardino counties.

Socioeconomic Analysis
The proposed changes are administrative in nature and are not expected to impact emissions or costs.

Implementation and Resources
Staff does not anticipate the need for additional resources to adequately implement and enforce the proposed rule.

ATTACHMENT A
SUMMARY OF PROPOSED AMENDMENTS

- ***Source Testing***
  Require source testing, approved by the Executive Officer, to demonstrate compliance.

- ***Permitting***
  Sources subject to Rule 1175 that utilize a control device to comply with the rule are required to obtain a federally enforceable permit, such as a Title V operating permit, that includes any identified critical operational techniques and parameters.

- ***Prohibition of Use***
  Clarify that the prohibition for methylene chloride and chlorofluorocarbons (CFC) applies to all manufacturing operations subject to the rule excluding those specifically approved as acceptable alternatives under 40 CFR Part 82 Subpart G – Significant New Alternatives Policy Program.

- ***Record keeping***
  Records of operations and emission control system techniques and parameters shall be maintained for five years to demonstrate compliance and maintain consistency with Title V permit requirements.

RESOLUTION NO.

A Resolution of the South Coast Air Quality Management District (AQMD) Governing Board certifying the Notice of Exemption for the proposed amendments to Rule 1175 – Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products.

A Resolution of the AQMD Governing Board amending Proposed Amended Rule 1175 – Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products.

WHEREAS, the AQMD Governing Board finds and determines that the proposed amendments to Rule 1175 are considered a "project" pursuant to the California Environmental Quality Act (CEQA); however, AQMD staff reviewed the proposed project and determined with certainty that the proposed amendments are exempt from the requirements of CEQA pursuant to CEQA Guidelines §15061 (b)(3) and have prepared a Notice of Exemption (NOE); and

WHEREAS, the AQMD Governing Board voting on Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, has reviewed and considered the NOE prior to its certification; and

WHEREAS, the AQMD Governing Board has determined that a need exists to amend Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, to address the concerns expressed by the U.S. Environmental Protection Agency in their disapproval of the September 2007 amendment; and

WHEREAS, the AQMD Governing Board of the South Coast Air Quality Management District obtains its authority to adopt this proposed amended rule from Sections 39002, 40000, 40001, 40440, 40702 and 41508 of the California Health and Safety Code; and

WHEREAS, the AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, as proposed to be adopted is written or displayed so that its meaning can be easily understood by the persons directly affected by it; and

WHEREAS, the AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, as proposed to be adopted, is in harmony with, and not in conflict with or contradictory to, existing federal or state statutes, court decisions, or regulations; and

WHEREAS, the AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, as proposed to be adopted, does not impose the same requirements as any existing state or federal regulation and the proposed rule is necessary and proper to execute the powers and duties granted to, and imposed upon, the District; and

WHEREAS, the AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, as proposed to be adopted, references the following statutes which the AQMD hereby implements, interprets or makes specific; Health and Safety Code 40001(a) and (b) (air quality standards and air pollution episodes); 40702 (adoption of rules and regulations), and 40440 (rules and regulations to carry out the air quality management plan and to require best available retrofit control technology); and

WHEREAS, the AQMD Governing Board has determined that a Socioeconomic Impact Assessment is not required, pursuant to Health and Safety Code Section 40440.8 or 40728.5, because these amendments do not have a significant impact on air quality or emissions limitations; and

WHEREAS, a public hearing has been properly noticed in accordance with the provisions of Health and Safety Code Section 40725; and

WHEREAS, the AQMD Governing Board has held a public hearing in accordance with all provisions of law; and

WHEREAS, the AQMD Governing Board specifies the manager of Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, as the custodian of the documents or other materials which constitute the record of proceedings upon which the adoption of this proposed amendment is based, which are located at the South Coast Air Quality Management District, 21865 Copley Drive, Diamond Bar, California; and

WHEREAS, the AQMD Governing Board finds and determines, taking into consideration the factors in Section (d)(4)(D) of the Governing Board Procedures, that the modifications adopted which have been made to Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, since notice of public hearing was published do not significantly change the meaning of the proposed amended rule within the meaning of Health and Safety Code Section 40726; and

WHEREAS, the AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, should be amended for the reasons contained in the Final Staff Report; and

NOW, THEREFORE, BE IT RESOLVED, that the AQMD Governing Board does hereby certify the Notice of Exemption for Rule 1175, as proposed to be amended, is completed in compliance with CEQA Guidelines §15002 (k)(1) - Three Step Process and §15061(b)(3) – Review for Exemption (General Rule Exemption). This information was presented to the Governing Board, whose members reviewed, considered, and approved the information therein prior to acting on the proposed amendments.

BE IT FURTHER RESOLVED, that the AQMD Governing Board does hereby adopt, pursuant to the authority granted by law, Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, as set forth in the attached and incorporated herein by reference.

_____ _____

Date Clerk of the Boards

(Adopted November 3, 1989)(Amended January 5, 1990)
(Amended May 13, 1994)(Amended September 7, 2007)
(Proposed Amended Rule November 5, 2010)

PROPOSED AMENDED RULE 1175. CONTROL OF EMISSIONS FROM THE MANUFACTURE OF POLYMERIC CELLULAR (FOAM) PRODUCTS

(a) Applicability

This rule shall apply to polymeric cellular products manufacturing operations including but not limited to expandable polystyrene, extruded polystyrene, ~~foam~~ polyurethane, isocyanurate and phenolic foam operations. All steps of the manufacturing operation and the storage of the final product for a maximum of 48 hours are subject to the requirements of this rule.

(b) Definitions

For the purpose of this rule, the following definitions shall apply:

(1) APPROVED EMISSION CONTROL SYSTEM means any system used to reduce manufacturing and storage emissions and consists of an emission collection system and a control device, which are approved, in writing, by the Executive Officer, that has been demonstrated to perform and operate according to the following provisions:

(A) The emission collection system shall collect at least 90 percent by weight of the manufacturing emissions; and

(B) The emission collection system shall collect at least 90 percent by weight of the storage emissions; and

(C) The control device shall reduce emissions from the emission collection system by at least 95 percent, by weight.

(2) BLOWING AGENT means a liquid, gaseous or solid material that facilitates the formation of a cellular product from raw polymeric material.

(3) CERTIFICATE OF ANALYSIS is a written document that cites the range of pentanes in expandable polystyrene bead, expressed as the percentage by weight of a manufactured bead-lot, prior to shipment from the manufacturer. It also contains the name of the manufacturer, a bead-lot number, and grade and type identifiers, along with a signature of an officer or an officer's designee of the bead-lot manufacturer.

(4) CHLOROFLUOROCARBON (CFC) is any chlorinated fluorinated compound of carbon., ~~excluding;~~

~~chlorodifluoromethane (HCFC-22),~~
~~dichlorotrifluoroethane (HCFC-123),~~
~~tetrafluoroethane (HFC-134a),~~
~~dichlorofluoroethane (HCFC-141b),~~
~~chlorodifluoroethane (HCFC-142b)~~
~~2-chloro-1,1,1,2-tetrafluoroethane (HCFC-124),~~

(5) EXEMPT COMPOUNDS (see Rule 102 - Definition of Terms)

(6) EXPANDABLE POLYSTYRENE (EPS) MOLDING OPERATIONS consist of a series of processes, where polystyrene beads and blowing agent are expanded by exposure to steam or any other expansion agent and processed through cup, block or shape molding into low-density, closed cell, cellular products. EPS products include but are not limited to drinking cups, insulation board, packaging material, and ice chests.

(7) EXTRUDED POLYSTYRENE (XPS) FOAM OPERATIONS consist of a series of processes, where a blowing agent is injected into molten polystyrene and upon exit of the extrusion die the blowing agent vaporizes thus expanding the molten resin into foam, where it expands in both thickness and width, and includes directly associated processes that incorporate reprocessed material into XPS products. XPS products include but are not limited to food containers and insulation foams used in the construction of structures for both residential and commercial buildings, such as under concrete slabs, roofing, decks, steel and wood framed wall sheathing.

(~~7~~8) LOW-PENTANE BEAD is an expandable polystyrene bead containing pentane as a blowing agent with an upper limit less than 4.0 percent by weight, prior to shipment, as certified upon delivery by an accompanying bead lot manufacturer's Certificate of Analysis.

(~~8~~9) MANUFACTURING EMISSIONS are any emissions of VOC, CFC, or methylene chloride that occur during the manufacturing operation.

(~~9~~10) MANUFACTURING OPERATION means every step of the processing of a polymeric material from the delivery of the raw material, until the storage of the final cellular product.

(~~10~~11) MID PENTANE BEAD is an expandable polystyrene bead containing pentane as a blowing agent within the range of 4.0 to 5.2 percent by weight, prior to shipment, as certified upon delivery with an accompanying bead lot manufacturer's Certificate of Analysis.

(~~11~~12) RAW MATERIAL means all polystyrene beads, polyurethane, reprocessed material and blowing agent used in the manufacture of polymeric cellular products.

(13) REPROCESSED MATERIAL means all regrind trim, scrap or recycled material.

(~~12~~14) RIGID POLYURETHANE is a closed cell polyurethane, primarily manufactured as rigid slabstock, laminated boardstock, field spray foam or pour-in-place foam.

(~~13~~15) STORAGE EMISSIONS are VOC emissions occurring for a maximum of 48 hours after the polymeric cellular foam product is manufactured.

(~~14~~16) VOLATILE ORGANIC COMPOUND (VOC) ~~(see Rule 102 - Definition of Terms)~~ is as defined in Rule 102.

(c) Emission Control Requirements

(1) Manufacturing Operations, Excluding Expandable Polystyrene ~~(EPS)~~ Molding Operations and Extruded Polystyrene Foam Operations

(A) ~~By January 1, 1994, each~~ No polyurethane operation subject to the~~is~~ rule shall ~~discontinue its~~ use ~~of~~ any ~~CFCs,~~ VOCs~~, or methylene chloride~~.

(B) Each manufacturing operation, excluding rigid polyurethane operations shall reduce yearly emissions from its 1988 emissions baseline, based on Rule 301 emission fees filing, by 100 percent, beginning calendar year 1994.

(2) Expandable Polystyrene ~~(EPS)~~ Molding and Extruded Polystyrene Foam Operations

The owner or operator of an expandable polystyrene ~~(EPS)~~ molding operation or an extruded polystyrene foam operation shall demonstrate, to the satisfaction of the Executive Officer, manufacturing emissions and post-manufacturing emissions, assuming all the blowing agent is released from the product, are less than 2.4 lbs per 100 lbs of raw material processed.

(3) The owner or operator of any polymeric cellular manufacturing operation, subject to the requirements of paragraphs (c)(1) or (c)(2), shall submit a plan to be approved by the Executive Officer, that demonstrates compliance with paragraph (c)(1) or (c)(2).

(4) The owner or operator of any polymeric cellular manufacturing operation that has not achieved the requirements specified in paragraph (c)(1), (c)(2), or (c)(3) shall:

(A) Submit permit applications for the installation of an emission control system within four months of the date that compliance with such requirement was not achieved; and

(B) Within twelve months of failing to meet the requirements of paragraph (c)(1), (c)(2), or (c)(3), the following provisions must be satisfied:

(i) An approved emission control system is installed and operated with all sources of manufacturing emissions collected and reduced according to subparagraphs (b)(1)(A) and (b)(1)(C); this system, including any critical operational techniques and parameters (e.g., minimum temperature and time in aging/curing areas venting to the control system, if applicable), must be incorporated in a federally enforceable permit, such as a Title V operating permit, as approved by the Executive Officer; and

(ii) All sources of storage emissions from the final manufactured product are collected and reduced according to subparagraphs (b)(1)(B) and (b)(1)(C) for at least:

(I) 48 hours, in the case of expandable polystyrene molding operations that process more than 800,000 pounds per calendar year of raw material; or

(II) 24 hours, in the case of all other manufacturing operations.~~; or~~

(~~iii~~5) Expanded ~~Polystyrene~~ polystyrene ~~(EPS)~~ block molding operations may, in lieu of complying with the specific control requirements of clauses (c)(4)(B)(i) and (c)(4)B)(ii), collect and reduce, ~~through a combination of emission control systems and operational techniques, as approved by the Executive Officer,~~ manufacturing emissions by at least 93 percent overall by weight (the product of capture and control device efficiencies), provided, at least 60 percent of the annual ~~EPS~~ expanded polystyrene block throughput is manufactured with low-pentane bead and the remainder with mid-pentane bead. Any owner or operator of a facility who elects to comply using this alternate compliance method shall

demonstrate the requisite 93 percent reduction through a source test approved in writing by the Executive Officer. Facilities with a Title V permit shall repeat such demonstration every five (5) years. This alternate compliance method, including any critical operational techniques and parameters (e.g., minimum temperature and time in aging/curing areas venting to the control system, if applicable), must be incorporated in a federally enforceable permit, such as a Title V operating permit, as approved by the Executive Officer.

(6) The owner or operator of a facility utilizing an approved emission control system shall conduct source testing, to be approved in writing by the Executive Officer, to demonstrate compliance with paragraphs (c)(2) or (c)(4). Facilities with a Title V permit shall repeat such demonstration every five (5) years.

(d) Prohibition of Use

No polymeric cellular product operation subject to this rule shall use methylene chloride, or any CFC, unless specifically approved as an acceptable alternative under 40 CFR Part 82 Subpart G – Significant New Alternatives Policy Program.

(~~d~~e) Exemptions

(1) The provisions of paragraph (c) shall not apply to any:

(A) Expandable polystyrene operation that processes less than 200 pounds per day of raw material.

(B) Rigid polyurethane operation that processes less than 1,000 pounds per day of raw material.

(2) The provisions of clause (c)(4)(B)(ii) shall not apply to any facility that only manufactures:

(A) ~~rigid~~ Rigid polyurethane foam; or

(B) Expanded polystyrene ~~EPS~~ foam and the highest concentration of the blowing agent in the cellular product is 1.8 percent or less by weight within 15 minutes of completion of the manufacturing operation. Verification of the concentration shall be demonstrated annually, pursuant to a written protocol submitted to and approved by the Executive Officer.

(~~e~~f) Recordkeeping

(1) Any owner or operator subject to this rule or claiming an exemption under ~~paragraph~~ subdivision (~~d~~e) shall maintain a daily record of operations, including but not limited to the amount of raw material processed, the equipment used, and the type of blowing agent used. Such records shall be retained in the operator's files for a period of ~~two~~ five (5) years and be made available to the Executive Officer upon request.

(2) Owners and/or operators using any emission control system as a means of complying with this rule shall maintain daily records of the operation and maintenance of the emission control system. These records shall include key system operating parameters such as temperatures, pressures, flowrates, and other measures needed to demonstrate compliance with paragraphs (c)(4), (c)(5) and (c)(6). Such records shall be retained in the operator's files for a period of five (5) years and be made available to the Executive Officer upon request.

(~~f~~g) Methods of Analysis

All applicable methods of analysis shall be as cited in paragraphs (~~f~~g)(1) through (~~f~~g)(~~6~~4) below, or any other applicable method approved by the Executive Officer, the United States Environmental Protection Agency (U.S. EPA), and the California Air Resources Board (CARB), provided the approved alternative method is equivalent to those listed ~~above~~below.

(1) Determination of VOC Content

The VOC content of materials subject to the provisions of this rule shall be determined by the following methods:

(A) U.S. EPA Reference Method 24 (Code of Federal Regulations Title 40 Part 60, Appendix A). The exempt solvent content shall be determined by SCAQMD Method 303 (Determination of Exempt Compounds) contained in the SCAQMD "Laboratory Methods of Analysis for Enforcement Samples" manual; or,

(B) SCAQMD Method 304 [Determination of Volatile Organic Compounds (VOCs) in Various Materials] contained in the SCAQMD "Laboratory Methods of Analysis for Enforcement Samples" manual.

(C) Exempt Perfluorocarbon Compounds

The following classes of compounds will be analyzed as exempt compounds for compliance with subdivision (c), only when

manufacturers specify which individual compounds are used in the manufacture of polymeric cellular products:

cyclic, branched, or linear, completely fluorinated alkanes;

cyclic, branched, or linear, completely fluorinated ethers with no unsaturations;

cyclic, branched, or linear, completely fluorinated tertiary amines with no unsaturations; and

sulfur-containing perfluorocarbons with no unsaturations and with sulfur bonds only to carbon and fluorine.

In addition, the manufacturers must identify the U.S. EPA, CARB, and SCAQMD approved test methods used to quantify the amount of each exempt compound.

(2) Determination of Pentanes in Expandable Styrene Polymers

The weight percent pentane in expandable polystyrene polymer shall be determined by SCAQMD Method 306 (Analysis of Pentanes in Expandable Styrene Polymers) contained in the SCAQMD "Laboratory Methods of Analysis for Enforcement Samples" manual.

(3) Determination of Efficiency of Emission Control System

(A) Capture efficiency specified in paragraph (b)(1) or ~~phrase~~ paragraph (c)(45)~~(B) (iii)~~ shall be determined by the procedures presented in the U.S. EPA technical guidance document "Guidelines for Determining Capture Efficiency, January 9, 1995", or U.S. EPA Methods 204 A-F.

(B) The efficiency of the control device of the emission control system specified in paragraph ~~-~~(b)(1) or ~~phrase~~ paragraph (c)(45)~~(B) (iii)~~ and the VOC content in the control device exhaust gases, measured and calculated as carbon, shall be determined by U.S. EPA Test Methods 25, 25A, SCAQMD Method 25.1 (Determination of Total Gaseous Non-Methane Organic Emissions as Carbon), or SCAQMD Method 25.3 (Determination of Low Concentration of Non-Methane Non-Ethane Organic Compound Emissions from Clean Fueled Combustion Sources) as applicable. U.S. EPA Test Method 18, or ARB Method 422 shall be used to determine emissions of exempt compounds.

(4) Multiple Test Methods

When more than one test method or set of test methods are specified for any testing, a violation of any requirement of this rule established by any one of the specified test methods or set of test methods shall constitute a violation of the rule.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

EXECUTIVE SUMMARY

Proposed Amended Rule 1175 – Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products has been developed to address the concerns the U.S. Environmental Protection Agency (U.S. EPA) expressed when they disapproved the September 2007 amendment because of rule deficiencies. The specific deficiencies described by U.S. EPA are as follows:

1. The rule must require demonstration, through source testing approved in writing by the Executive Officer, that the systems and techniques in place at a facility achieve 93% collection and reduction of emissions for source complying with paragraph (c)(5) [was clause (c)(4)(B)(iii)].
2. The rule must clarify that all operational techniques and parameters needed to achieve compliance with paragraph (c)(5) [was clause (c)(4)(B)(iii)] be clearly defined, enforceable through a federally enforceable permit and identified in Rule 1175, where possible.
3. The rule must clarify that all operational techniques and parameters needed to achieve 90% collection and 95% destruction to comply with clauses (c)(4)(B)(i) and (c)(4)(B)(ii) be clearly defined, enforceable through a federally enforceable permit and identified in Rule 1175, where possible.

Staff proposes the following requirements for Proposed Amended Rule 1175:

- Require source testing, approved by the Executive Officer, to demonstrate compliance with clauses (c)(4)(B)(i), (c)(4)(B)(ii) and paragraph (c)(5) [was clause (c)(4)(B)(iii)].
- Require record keeping to verify that all operational techniques and parameters needed to ensure continued utilization of operational techniques used to comply with clauses (c)(4)(B)(i), (c)(4)(B)(ii) and paragraph (c)(5).
- Clarify that the prohibition for methylene chloride and chlorofluorocarbons (CFC) applies to all manufacturing operations subject to the rule excluding those specifically approved as acceptable alternatives under 40 CFR Part 82 Subpart G – Significant New Alternatives Policy Program.
- Correct typographical errors associated with Methods of Analysis.
- Make minor clarifications and editorial corrections to the rule.

The proposed changes are administrative in nature and are not expected to impact emissions or costs.

CHAPTER 1: BACKGROUND

INTRODUCTION

REGULATORY HISTORY

INTRODUCTION

In May 2010, U.S. EPA disapproved a revision to the District portion of the State Implementation Plan because of concerns about VOC emissions from polymeric foam manufacturing operations. The specific deficiencies are described below under Regulatory History.

REGULATORY HISTORY

Rule 1175 was adopted November 3, 1989 and has since been amended three times with the last amendment on September 7, 2007. The rule prohibits the use of chlorofluorocarbons (CFCs), Volatile Organic Compounds (VOCs) and methylene chloride in polymeric cellular foam product operations except for expandable polystyrene molding and extrudable polystyrene foam operations. The rule controls VOC emissions of expandable polystyrene molding operations and extrudable polystyrene foam operations by either requiring control devices to capture VOC emissions or by limiting emissions to 2.4 pounds of VOC emitted per 100 pounds of product produced.

The September 7, 2007 rule amendment allowed for equivalent emissions collection and control by over-controlling the manufacturing emissions, in lieu of controlling their less cost-effective block storage areas. On May 10, 2010, as published in the Federal Register [FR Doc 2010-109121], U.S. EPA announced their disapproval to the amendment. According to U.S. EPA, some rule provisions do not satisfy the requirements of section 110 and part D of the Clean Air Act. Specifically:

1. The rule must require demonstration, through source testing approved in writing by the Executive Officer, that the systems and techniques in place at a facility achieve 93% collection and reduction of emissions for sources complying with clause (c)(4)(B)(iii) [revised to be paragraph (c)(5)].

2. The rule must clarify that all operational techniques and parameters needed to achieve 93% control to comply with paragraph (c)(4)(B)(iii) [revised to be paragraph (c)(5)] must be clearly defined and enforceable through a federally enforceable permit such as a Title V operating permit. Rule 1175 should also be revised where possible to identify these parameters.

3. The rule must clarify that all operational techniques and parameters needed to achieve 90% collection and 95% destruction to comply with paragraphs (c)(4)(B)(i) and (c)(4)(B)(ii) must be clearly defined and enforceable through a federally enforceable

permit such as a Title V operating permit. Rule 1175 should also be revised where possible to identify these parameters.

U.S. EPA also included recommendations to further improve the rule that do not affect their current action. In response to their request, AQMD staff has made minor clarifications and editorial corrections to the rule to enhance the clarity of the rule.

CHAPTER 2: SUMMARY OF PROPOSED AMENDED RULE 1175

OVERVIEW

Staff proposes to address the deficiencies identified by the U.S. EPA. In addition, the rule will incorporate the administrative recommendations included in U.S. EPA's technical support document.

PROPOSED MODIFICATIONS TO RULE 1175

Applicability

A minor clarification is included to make the terms used to describe application operations more consistent. Specifically, the term "Extruded Polystyrene" will be used consistently throughout the rule and associated documentation.

Definitions

The definition for Chlorofluorocarbon had been modified to include previously excluded CFCs: chlorodifluoromethane (HCFC-22), dichlorotrifluoroethane (HCFC-123), tetrafluoroethane (HFC-134a), dichlorofluoroethane (HCFC-141b), chlorodifluoroethane (HCFC-142b) and 2-chloro-1,1,1,2-tetrafluoroethane (HCFC-124). All CFCs used in operations subject to Rule 1175 are prohibited unless specifically approved as acceptable alternatives under 40 CFR Part 82 Subpart G – Significant New Alternatives Policy Program.

A definition is included for Extruded Polystyrene (XPS) Foam Operations. These operations were previously included under Expandable Polystyrene (EPS) Molding Operations even though the definition did not adequately describe them. Rather than broadening the definition for Expandable Polystyrene Molding Operations, the new definition is included.

Reprocessed Material has been defined and the definition for Raw Material has been clarified to indicated that the use of regrind recycled, scrap or trim foam may be included as a raw material.

Requirements

The requirements applicable to Extruded Polystyrene (XPS) Foam Operations have been clarified. The requirements are unchanged but the inclusion of the definition necessitates explicitly referencing the new term in paragraphs (c)(1) and (c)(2).

Sources subject to Rule 1175 that utilize a control device to comply with the rule are required to obtain a federally enforceable permit from the District. At the time of permit issuance, the Executive Officer, in writing, will impose specific permit conditions reflecting the necessary parameters needed to achieve this level of control. The specific parameters may include, but

are not limited to, establishing specific temperatures and pressure limits for aging rooms, establishing volumetric flow rates into a control device and requiring a minimum operating temperature for the control device. Failure to maintain the control device in good operating condition, including conditions imposed by the Executive Officer, will be considered a violation of Rule 1175.

Facilities utilizing control equipment to comply with the provisions of the proposed rule will be required to conduct source testing, approved in writing by the Executive Officer, to demonstrate the collection and control efficiency. Such testing is routinely required as part of the permitting process.

The prohibition of using methylene chloride and CFCs has been relocated to subdivision (d) to clarify that the prohibition applies to all polyurethane operations subject to the rule including expandable polystyrene molding operations and extruded polystyrene foam operations. All CFCs used in operations subject to Rule 1175 are prohibited unless specifically approved as acceptable alternatives under 40 CFR Part 82 Subpart G – Significant New Alternatives Policy Program. This will provide consistency between Rule 1175 and federal requirements. At this time the only use of CFCs approved in foam products is HCFC-141b for space vehicle, nuclear, defense and research and development for foreign customers (see Appendix M to Subpart G—Unacceptable Substitutes Listed in the September 30, 2004 Final Rule, Effective November 29, 2004).

Monitoring, Recordkeeping and Reporting Requirements

Records of operations and emission control system parameters shall be maintained for five years to maintain consistency with Title V permit requirements.

Methods of Analysis

Typographical errors are corrected in subdivision (g) of the proposed rule. Specifically, the paragraphs referenced shall be (g)(1) through (g)(4) rather than (g)(6) which does not exist. Also, the alternative methods must be equivalent to the methods that are listed below, rather than above the lead-in language of the rule.

CHAPTER 3: IMPACT ASSESSMENT

INTRODUCTION

EMISSION IMPACT ASSESSMENT

SOCIOECONOMIC IMPACT ASSESSMENT

POTENTIAL ENVIRONMENTAL IMPACTS

DRAFT FINDINGS UNDER CALIFORNIA HEALTH AND SAFETY CODE 40727

COMPARATIVE ANALYSIS

COMMENTS AND RESPONSES

INTRODUCTION

Rule 1175 applies to polymeric cellular products manufacturing operations and includes but is not limited to expandable polystyrene, extruded polystyrene, polyurethane, isocyanurate and phenolic foam operations. This amendment is an administrative change request by the U.S. EPA and is not expected to affect emission impacts.

EMISSION IMPACT ASSESSMENT

The proposed amendments are administrative in nature and will not impact the emission inventory nor result in any emission reductions.

SOCIOECONOMIC IMPACT ASSESSMENT

The proposed amendments to Rule 1175 do not significantly affect air quality or emission limitations and therefore a socioeconomic impact analysis pursuant to California Health and Safety Code Sections 40440.8 and 40728.5 is not required.

Cost and Cost-Effectiveness

The proposed amendments will not result in additional costs to industry. Source testing and record keeping are routinely required in permit conditions applied to control devices. Since there is no additional cost and no change in emissions, cost effectiveness is not applicable.

Incremental Cost-Effectiveness

Under Health and Safety Code Section 40920.6, the AQMD is required to perform an incremental cost analysis when adopting a Best Available Retrofit Control Technology (BARCT) rule or feasible measure required by the California Clean Air Act. To perform this analysis, the AQMD must (1) identify one or more control options achieving the emission reduction objectives for the proposed rule, (2) determine the cost effectiveness for each option, and (3) calculate the incremental cost effectiveness for each option. To determine incremental costs, the AQMD must "calculate the difference in the dollar costs divided by the difference in the emission reduction potentials between each progressively more stringent potential control option as compared to the next less expensive control option."

Proposed Amended Rule 1175 addresses administrative issues identified by the U.S. EPA. The proposed amended rule does not implement a BARCT rule or a feasible measure required by the California Clean Air Act. Thus an incremental cost analysis is not required.

POTENTIAL ENVIRONMENTAL IMPACTS

CEQA applies only to projects which may have a significant effect on the environment. Staff has reviewed the proposed amendments and, pursuant to CEQA Guidelines § 15002(k)(1) – Three Step Process, has determined that the proposed amendments to Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products are exempt from CEQA pursuant to CEQA Guidelines § 15061(b)(3) – Review for Exemption. If approved by the Governing Board, a Notice of Exemption (NOE) will be prepared for the proposed project pursuant to CEQA Guidelines §15062 – Notice of Exemption, and mailed to the county clerks of Los Angeles, Orange, Riverside, and San Bernardino counties.

DRAFT FINDINGS UNDER CALIFORNIA HEALTH AND SAFETY CODE 40727

Health and Safety Code Section 40727 requires that prior to adopting, amending or repealing a rule or regulation, the AQMD Governing Board shall make findings of necessity, authority, clarity, consistency, non-duplication, and reference based on relevant information presented at the hearing. The draft findings are as follows:

Necessity – The AQMD Governing Board has determined that a need exists to amend Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products to address the deficiencies identified by the U.S. EPA.

Authority - The AQMD Governing Board obtains its authority to adopt, amend, or repeal rules and regulations from Health and Safety Code Sections 39002, 40000, 40001, 40440, 40441, 40702 and 41508.

Clarity - The AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, is written and displayed so that the meaning can be easily understood by persons directly affected by them.

Consistency - The AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, is in harmony with, and not in conflict with or contradictory to, existing statutes, court decisions, federal or state regulations.

Non-Duplication - The AQMD Governing Board has determined that Proposed Amended Rule 1175 - Control of Emissions from the Manufacture of Polymeric Cellular (Foam) Products, does not impose the same requirement as any existing state or federal regulation,

and the proposed amendments are necessary and proper to execute the powers and duties granted to, and imposed upon, the AQMD.

Reference - In adopting this regulation, the AQMD Governing Board references the following statutes which the AQMD hereby implements, interprets or makes specific: California Health and Safety Code sections 40001, 40440, and 40702.

COMPARATIVE ANALYSIS

Health and Safety Code Section 40727.2 requires a written analysis comparing the proposed rule with existing federal and AQMD regulations. Federal regulations do not regulate VOC emissions from the manufacture of polymeric cellular (foam) products. However, federal regulations do prohibit the use of certain ozone-depleting substances under section 610(d) of the Clean Air Act (CAA). Specifically, Class I and Class II ozone depleting substances (ODS) including CFCs, halons, carbon tetrachloride and methyl chloroform, methyl bromide and most hydrofluorocarbons (HCFCs). Section 612 of the CAA required EPA to establish the Significant New Alternatives Policy (SNAP) program to evaluate alternatives to ODS making it unlawful to substitute alternatives that present adverse effects to human health or the environment where another alternative has been identified that reduces risk and is available. Under the SNAP program HCFC-124, HCFC-22 and HCFC-142b have been determined to be unacceptable substitutes. HCFC-141b has been determined to be an unacceptable substitute in certain foam blowing applications. The proposed rule will prohibit the use of all CFCs except those specifically approved under the SNAP program. At this time, only the use of HCFC 141b for space vehicle, nuclear, defense and research and development for foreign customers has been approved.

COMMENTS AND RESPONSES

The following comments and AQMD staff responses were in response to the concerns of U.S. EPA staff, from their September 30, 2009 e-mail.

Comment: While Rule 1175 applies to polystyrene foam extrusion operations, it does not explicitly reference these operations as it does polystyrene molding and block making operations. Future revisions should clarify which requirements also apply to polystyrene foam extrusion.

Staff Response: *A definition for Extruded Polystyrene Molding Operations (polystyrene extrusion operations) has been included in the proposed amendments. The proposal also explicitly references provisions applicable to such operations.*

Comment: Please revise paragraph (c)(2) to clarify whether polystyrene foam extrusion may include reprocessed material when demonstrating compliance with the limit of 2.4 pounds VOC per 100 pounds raw material processed.

Staff Response: *The definition for Raw Material will specifically include reprocessed material and paragraph (c)(2) has been clarified to note that Extruded Polystyrene Molding Operations may utilize this alternative compliance option.*

Comment: Note two potential typographical errors in the introductory paragraph of section (f). The first sentence references paragraphs (f)(1) through (f)(6), although the rule ends with (f)(4). The last sentence reads, "…provided the approved alternative method is equivalent to those listed above," but we find no methods listed above.

Staff Response: *The typographical errors have been corrected.*

Comment: In developing the additional compliance option in paragraph (c)(4)(iii) [revised to paragraph (c)(5)], SCAQMD relied on data generated using procedures designed to measure emissions from highway vehicles. In June 2005, EPA supported an expanded polystyrene block molding facility's plan to complete these tests for a separate purpose, and EPA did not expect that the results would be used to support this rule amendment. As a result, we strongly recommend that SCAQMD reevaluate the compliance option in light of: (a) the small number of polystyrene block tests that form the technical basis for the compliance option; and (b) a report released in March 2009 by the Alliance of Foam Packaging Recyclers and EPS Manufacturers Association, entitled "Pentane Emissions Profile for Expanded Polystyrene Foam Manufacturing Industry", which suggests considerably higher emissions during block storage.

Staff Response: *According to the Staff Report for the previous amendment to Rule 1175, the expanded polystyrene block testing "shows that the alternative compliance option is at a minimum equivalent to the current rule and in most cases is superior in terms of emission reduction benefits when compared to the current requirement for capture and destruction of manufacturing and 48-hour storage emissions. In addition, the*

pollution prevention element included in the proposed compliance option, requiring the use of lower pentane bead will further ensure that the proposed alternative provides superior environmental benefit." In the report cited by U.S. EPA, "the type of pentane isomers used in the blowing agent were not identified for the industry data set provided; therefore, the potential effect of the pentane isomers on residual pentane content was not considered. Insufficient support data were provided to quantify any difference in pentane losses on a weight percentage basis due to low pentane or regular pentane beads for like applications and product densities." The District believes that the alternative control option combined with lower pentane bead requirement will not lead to backsliding. The report cited by U.S. EPA does not have any data that contradicts that conclusion because it does not address low pentane beads.

Comment: Is it possible for a facility to utilize multiple compliance options to demonstrate compliance with the rule provisions?

Staff Response: *A facility may utilize multiple compliance options to demonstrate compliance. Facilities seeking such alternatives will be required to submit permit applications for engineering review, source test each scenario requested, accept federally-enforceable permits with critical operation techniques and parameters incorporated into the permit and maintain daily records demonstrating compliance.*

Comment: Is reprocessed material included as raw material?

Staff Response: *Raw material does include reprocessed material such as regrind trim, scrap or recycled materials. The definition for Raw Material has been clarified to include reprocessed material and a definition for Reprocessed Material has been included in the proposed rule.*

Comment: The alternative compliance option under (c)(5) should be available to shape molding operations. Shape molders have similar issues as the block molders do when it comes to product density, inability to construct 48-hour controlled enclosures due to leased property and limited space and the need to process some higher pentane material while processing mostly low-to-mid-range pentane material.

Staff Response: *The data currently provided to demonstrate equivalence is insufficient to make a determination to include shape molding operations under the*

alternative compliance option. Further testing is necessary to establish the collection efficiency of the control equipment and emissions lost during the initial 48 hours of storage. Staff will continue to work with interested parties to determine if the alternative compliance option can be made available to shape molding operations.

Comment: Paragraph (c)(1) prohibits the use of CFCs excluding HCFC-22, HCFC-123, HFC-134a, HCFC-141b, HCFC-142b and HCFC-124. Therefore the rule allows the HCFCs and HFCs listed above. However, the use of HCFC-22, HCFC-124, HCFC-141b and HCFC-142b is in conflict with the ban of these chemicals in some foam manufacturing applications as U.S. EPA-approved foam blowing agents under the SNAP program. We recommend that the District clarifies that Rule 1175 is not in conflict with Federal requirements on prohibited foam blowing agents.

Staff Response: *The proposed rule has been modified to prohibit the use of all CFCs in foam operations except those specifically approved under the SNAP program. This will provide consistency between Rule 1175 and the federal requirements.*

Comment: The Preliminary Staff Report acknowledges that certain HCFCs are not allowed as foam blowing agents by the U.S. EPA. Specifically, the reports states in part:

> Under the SNAP program HCFC-124, HCFC-22 and HCFC-142b have been determined to be unacceptable substitutes. HCFC-141b has been determined to be an unacceptable substitute in certain foam blowing applications. With the exception of expanded polystyrene molding operations, Rule 1175 prohibits the use of CFCs. While the rule is silent regarding the use of CFCs in expanded polystyrene molding operations and HCFC in all applications, there is no direct conflict between Rule 1175 and federal regulations.

The above staff analysis may not be entirely accurate (or perhaps unclear). The rule prohibits CFCs but specifically allows the use of HCFC-22, HCFC-123, HFC-134a, HCFC-141b, HCFC-142b and HCFC-124. We suggest that the District provides additional

clarification on how the rule is not in conflict with U.S. EPA foam blowing agent SNAP regulations.

Staff Response: *We concur that the rule language and analysis provided were unclear regarding the use HCFC-22, HCFC-123, HFC-134a, HCFC-141b, HCFC-142b and HCFC-124. The proposed rule has been modified to prohibit the use of all CFCs in foam operations except those specifically approved under the SNAP program. This will provide consistency between Rule 1175 and the federal requirements.*

SUBJECT: **NOTICE OF EXEMPTION FROM THE CALIFORNIA ENVIRONMENTAL QUALITY ACT**

PROJECT TITLE: **PROPOSED AMENDED RULE 1175 – CONTROL OF EMISSIONS FROM THE MANUFACTURE OF CELLULAR FOAM PRODUCTS**

Pursuant to the California Environmental Quality Act (CEQA) Guidelines, the South Coast Air Quality Management District (SCAQMD) is the Lead Agency and has prepared a Notice of Exemption for the project identified above.

The SCAQMD has reviewed the proposed project pursuant to CEQA Guidelines §15002 (k)(1), the first step of a three-step process for deciding which document to prepare for a project subject to CEQA. Since it can be seen with certainty that the proposed project has no potential to adversely impact air quality or any other environmental area, it is exempt from CEQA pursuant to CEQA Guidelines §15061(b)(3) - Review for Exemption (General Rule Exemption).

A Notice of Exemption has been prepared pursuant to CEQA Guidelines §15062 - Notice of Exemption. The Notice of Exemption will be filed with the county clerks of Los Angeles, Orange, Riverside and San Bernardino counties immediately following the adoption of the proposed project.

Any questions regarding this Notice of Exemption should be sent to Barbara Radlein (c/o Planning, Rule Development and Area Sources) at the above address. Ms. Radlein can also be reached at (909) 396-2716. Mr. Michael Morris is also available at (909) 396-3282 to answer any questions regarding the proposed amendments.

Date: October 6, 2010

NOTICE OF EXEMPTION

To: *County Clerks*
Counties of Los Angeles, Orange,
Riverside and San Bernardino

From: *South Coast Air Quality Management District*
21865 Copley Drive
Diamond Bar, CA 91765

Project Title:
Proposed Amended Rule 1175 – Control of Emissions from the Manufacture of Cellular Foam Products

Project Location:
South Coast Air Quality Management District: the four-county South Coast Air Basin (Orange County and the non-desert portions of Los Angeles, Riverside, and San Bernardino counties) and the Riverside County portions of the Salton Sea Air Basin and Mojave Desert Air Basin.

Description of Nature, Purpose, and Beneficiaries of Project:
The proposed amendments to Rule 1175 – Control of Emissions from the Manufacture of Cellular Foam Products, are considered to be administrative in nature as they would remedy deficiencies in the September 2007 version of Rule 1175 as identified by the United States Environmental Protection Agency (USEPA) by requiring: 1) source testing, approved by the Executive Officer, to demonstrate compliance with clauses (c)(4)(B)(i) and (c)(4)(B)(ii), and paragraph (c)(5) [originally referred to as clause (c)(4)(B)(iii)]; and, 2) recordkeeping to verify that all operational techniques and parameters needed to ensure continued utilization of operational techniques used to comply with clauses (c)(4)(B)(i) and (c)(4)(B)(ii), and paragraph (c)(5). Other minor changes are proposed for clarity and consistency throughout the rule.

Public Agency Approving Project:
South Coast Air Quality Management District

Agency Carrying Out Project:
South Coast Air Quality Management District

Exempt Status:
Three-Step Process: CEQA Guidelines §15002 (k)(1)
General Rule Exemption: CEQA Guidelines §15061 (b)(3)

Reasons why project is exempt:
The project was reviewed and determined to have no potential to generate significant adverse impacts on the environment. Therefore, the SCAQMD has determined that the proposal is exempt from CEQA pursuant to CEQA Guidelines §15061 (b)(3) - Review for Exemption, since it can be seen with certainty that there is no possibility that the proposed project in question has the potential to have a significant adverse effect on the environment.
